Attacks of angina pectoris constitute a very definite clinical picture with which you are all quite familiar. Typically there is a sudden severe pain situated behind the lower sternum radiating perhaps to the neck or left shoulder or to the inner side of the left arm, associated with a strong sense of constriction of the chest, so that the breath is caught with difficulty and with a sense of great weakness and anxiety so that the patient feels that he will surely die. At the time of such an attack the patient is prostrated. The pulse may or may not be increased in rate but is often irregular. These attacks are very typical and are not difficult to recognize, either when they are seen or when the patient tells you about them, and I believe that to such attacks as these the term angina pectoris should be confined. Then we have a train of symptoms associated with coronary disease which differ somewhat from those of true angina. The pain, which is usually less severe, is a mid-line pain. Its characteristic seat is behind the lower sternum opposite the third and fourth intercostal spaces, at the xiphoid or in the epigastrium opposite the fifth intercostal space. Rarely it is felt as high as the second intercostal space. When severe it radiates and passes laterally to the left or right at these levels and may seem to pass through to the back. In the lesser manifestations or coronary disease seen early, there may be no pain at all but merely a sense of discomfort, felt especially under the lower sternum or in the epigastrium and not as the patient will say, "in the stomach." It is never a constant sensation, but comes in attacks, and these attacks either arise spontaneously when the patient is at rest or come on as the result of exercise, so that the patient must stop and rest until the discomfort passes off. It has a very peculiar character best described as a gripping or a sense of compression beneath the sternum. The pain occurring in cases of myocardial disease is of a different character from that of coronary origin, being mostly to the left of the mid-line and radiating to the region of the apex beat, or being felt only at the apex. It does not have the radiation to the back, neck or arm except when very severe, and is a more continued pain than the gripping paroxysmal pain of coronary disease. Its character is more aching even though it should be, as it sometimes is, very severe indeed. When these conditions cause pain there is nearly always objective dyspnoea, a very rare occurrence with coronary artery attacks.

The pain felt by neurotic patients and patients with hyperthyroidism is not in either case a mid-line pain, but lies to the left of the sternum, like the pain of cardiac disease, and is most often situated about the region of the apex beat. That these patients have typical areas of hyperalgesia may lead you to a stronger belief that organic disease is present, but you must not be deceived by this into a diagnosis of cardiac disease. These pains, like those of coronary disease, may be brought on or increased by exertion, but there is an irregularity of occurrence after exercise which is characteristic, and this taken with the lateral situation of the pain and the fact that it moves around, together with evidence of a neurotic make-up of the patient, should enable us to readily recognize the origin of the symptoms. It is important to remember that these pains do not occur with the milder forms of hyperthyroidism, so that the rapid pulse or tremor or some of the other signs or symptoms of Graves' disease will be pres-

* Read before the Southern California Medical Society, 65th Regular Annual Meeting in San Diego, 1922.

ent to help you. In looking over my records of cases of myocardial insufficiency I found fourteen cases that I have seen in the last year and a half in which the symptoms did not coincide with any of those above, and the true nature of the malady had not been suspected either by their physicians or by the patients themselves until the disease had progressed well toward a fatal termination. Nine of these patients have died and the other five are still under observation.

I have not included in these fourteen cases any case in which the symptoms attracted either the physician or the patient to the heart as the cause of the trouble, and wish to emphasize that none of these cases were considered heart cases until the disease was well progressed.

CASE REPORTS

Case I. Male 63—Had been a railroad official, now retired. Had complained for a number of years of indigestion. He had been treated by several physicians with no appreciable relief. He was generally advised that his malady was due entirely to his stomach and bowels and was dieted and given treatment along that line. One morning I happened to be at his home and was called into his room and found him deathly pale, covered with cold perspiration and unconscious. (This was the first time I had seen him professionally as he had been under the care of another physician.) He had arisen as usual in the morning and was feeling very well. He went into the bathroom to shave and suddenly fell and I was immediately asked to step in and see him. Upon examination his pulse was not felt at wrist and, listening over his heart, the heart beat was rapid and grossly irregular. As his pulse returned, a polygraphic tracing taken then showed the attack to be one of paroxysmal auricular fibrillation which soon subsided and the heart beat became perfectly regular except for an occasional premature auricular beat which soon disappeared, and I never found any irregularity in his pulse afterwards. He had no pain at any time and his only complaint was his indigestion and intestinal flatulence. He died in a neighboring city recently, and I will quote the following from a letter I received from his wife: "Mr. J. was very well all summer and we put off from month to month going down to see you. We had been out to Van Nuys all day, and after dinner he said: 'I feel exceptionally well tonight.' But a few minutes later gas began to bother him. I gave him soda but it didn't give him any relief. He had no pain in his heart but it beat very fast. He just said, 'I am so nervous, I can't stand it,' and became unconscious." I had this man under observation for some time after the first attack and outside of his heart being slightly enlarged there was nothing that would attract one's attention to it. The rate was normal, rhythm was regular. There were no abnormal sounds. There was no swelling of the feet, nor cough.

Case II. A man 54 years of age walked into my office complaining of pain in his stomach. He gave the following history: He had had a similar attack of indigestion, as he termed it, accompanied with severe pain while on the street two years ago and he was taken to the office of a chiropractor, who treated him for three weeks, during which time he was up and around. Since then he had been troubled a great deal with a sour stomach. He said that he ate too much, always having a good appetite. Under closer questioning he admitted having felt pain in the epigastrium after running, lifting, or going up hill. But all the time during the past two years he had done his work on his ranch and had been very well with the exception of his indigestion, which was always relieved immediately when he could get up the gas. Never had had any swelling of his feet; no cough except when he had a cold; never had rheumatism, tonsillitis or "flu," but his teeth were bad. He had had scarlet fever twenty years before, measles eight years before. On the day he consulted me he had carried two grips a considerable distance in Los Angeles and had taken the bus for San Diego. Soon after leaving Los Angeles he began to feel discomfort in his stomach, which increased, and when he arrived at Oceanside the discomfort had increased to such a degree that he went into the drug store to get something to make him vomit. After vomiting he felt better. He then stated that he knew it was his stomach, because he was always relieved after he could expel the gas. Examination revealed a well-nourished, well-muscled man, who had led an active outdoor life. His face was somewhat ashen, he was perspiring, held his hand over his epigastrium and complained of sense of fulness which was killing him and said if he could get something to expel the gas he would be all right, as he had had similar attacks before. His pulse was 84 regular, except for an occasional P. V. B. His B. pressure was 150 s. and 80 D. His apex was in the fifth interspace at the nipple line. The area of cardiac dullness extended 10½ cm. to the left of the median line and 3 cm. to the right. The first sound at the apex was split and second at apex was a trifle loud. At the base the aortic second was louder than the pulmonic. There were no murmurs anywhere except a slight after-tone to the aortic second heard at the ensiform. There were no rales to be heard in the chest. Urine S. S. showed a S. P. of 1026, no albumen, no casts. He was soon enough relieved to be taken home, although the distress never entirely ceased, and the next day there was some adema at the bases of the lungs, and he died suddenly while talking to his wife that evening. Post-mortem examination showed a heart somewhat enlarged, a thickened fibrous aorta with plagues, narrowed and sclerosed coronaries with complete occlusion of the left coronary by a thrombus.

Case III. Woman 60 years of age, who gave a history of abdominal symptoms for a number of years, always accompanied by gas on her stomach. She had been operated on for some pelvic disturbance and for appendicitis. She was now in the hospital to be operated on for a growth in the descending colon. I was called to examine her heart. I found a large, fleshy woman with some edema of her arms, giving a history of her feet swelling when she was up and around. She said she had a great deal of gas on her stomach and bowels, pain in her left side of abdomen, which had led up to where she was about to be operated for a growth in the descending colon. Upon examination, her pulse was 100, perfectly regular. B. P. 100, S. 70 D., area of cardiac dullness extended 11 cm. to the left and 4 cm. to the right of the median line. First sound at the apex was fairly good, the second at the apex was very faint, at the base the pulmonic second was much louder than aortic second. A faint systolic murmur was heard over the aortic second, but was not heard in the carotids. There were a few rales in both bases and a polygraphic tracing showed nothing except a variation in the output of the left ventricle. She said she felt quite well at present, except she was having a great deal of gas on her stomach. This patient was kept in bed and died suddenly about two weeks later, after excitement caused by transacting some important business. Dr. Thomson's report of post-mortem was as follows: Heart, large and moderately dilated, dark in color, right V. wall very thick, papillary muscles hypertrophied. Heart muscle very soft and friable, showed edema, was so soft that by a small amount of pressure the finger would go clear through. Chest contained fluid, both lower lobes of lung compressed. The descending colon was somewhat contracted, but showed no evidence of growth.

I have not the time to relate the histories of all these patients, but will give you a résumé of them. In eight cases the abdominal symptoms were accompanied at times with severe pain. Of this group of eight cases five of them had a blood pressure much below normal and in three the B. P. was slightly elevated. Six of this group are dead, all died very suddenly. Six of this group were males between the ages of fifty-four and seventy-six, and two were females between the same ages.

In none of these cases was there any valvular lesions of importance. The second group in which there were no attacks of pain, consisted of six patients, all males. Three of them had a low B. P. and in three of them the B. P. was slightly elevated. Three of this group are dead, all died rather suddenly according to reports; the exact termination I haven't been able to find out in all cases, as they died after leaving San Diego. Two of those that died had a low B. P. and in one it was elevated. Two of this group had pulsus alternans; in one the alternation followed a premature auricular beat, and in the other the alternation was continuous. The patient with continuous alternation is still alive, while the one with the short periods of alternation following the premature auricular beats is dead.

Of the whole series of fourteen cases only four of them showed a constant regular sequence of events in the cardiac cycle. Five of them showed periods of alternation in the polygraph tracing. Of these five three are dead and two are still living; of the remaining five cases one had an attack of paroxysmal auricular fibrillation; one had attacks of paroxysmal tachycardia with a short run of auricular flutter and is still alive, although he fell over in the park not long ago. Three showed only a premature V. beat, two of which are dead. Of the nine deaths all except two had some disturbance of the cardiac rhythm or pulsus alternans. In one of the cases with pulsus alternans, an electrocardognam showed a splintering of the Q. R. S. complex in lead 2.

Every one of the series had a heart enlarged to a point at or outside the nipple line, and eight of them had a B. P. below normal, six of whom are dead, while five of them showed a slightly elevated B. P., three of whom are dead. They all have this in common that months before the malignant nature of the malady had become apparent, mild gastric and abdominal symptoms had been complained of and the true nature of which had eluded some very competent observers.

The fourteen cases were all between the ages of fifty-four and seventy-eight, the greatest number being between the ages of fifty-four and sixty-five. There was no evidence of syphilis in any of them. None of them gave any evidence of gout, lead alcohol, nor the misuse of tobacco. I have not been able to trace any of these cases to a definite infectious origin. None of these cases were observed in my hospital work, all of them being observed in my private practice, which is the field par excellence for the observation of these cases.

The abdominal symptoms were the first signs of the myocardial insufficiency and none of them attributed any of their symptoms to their heart. In the mind of the patient all the symptoms were due to their stomach, otherwise why did the expulsion of gas give them relief. Some of them complained of fullness in the abdomen, having to loosen their clothing after eating and the escape of quantities of gas per rectum. The cardiovascular symptoms vary considerably after the case is well advanced. The pulse may be slow and regular, of good quality, and may be thus maintained throughout an attack accompanied by severe pain. One died and the pulse never went above 80 and suddenly stopped while I was counting it.

The presence of a myocardial insufficiency may first betray itself by some irregularity of the pulse or very low B. P. or the discomfort or pain following some exertion or eating. As the case advances it may develop alternation flutter, premature ventricular beats, premature auricular beats, paroxysmal tachycardia or parox, auricular fibrillation; the B. P. is more often abnormally low than high. In the two cases of which I was able to get a post-mortem, in one there was distinct evidence of aortic and coronary sclerosis, while in the other there was a soft friable edemitus heart muscle through which one could push his finger with slight pressure, with no mention of coronary disease. I think in this type the pain, if there is any, is due to the exhaustion of the heart muscle rather than to an interference with its blood supply, as probably occurs in the type with the attacks of paroxysms of pain. Also this latter group in the interval between the attacks are able to get around and feel comparatively well, while in the group without the pain there was a progressive failure of the heart muscle, and finally the symptoms of cardiac dilatation with edema, and so forth.

The first evidence that there is a cardiac factor as well as an abdominal one may be a sudden drop of the systolic B. P. to a point around 100. There is one school who think there is really an abdominal angina associated with sclerosis of the abdominal arteries, and another school who lean rather to the view that the abdominal symptoms are reflexes from thoracic pathological processes.

The pathological explanation of even true angina is still in dispute. The true coronarians see a degenerative process of the coronary arteries in all cases, while Osler, Graham-Steele and others cite autopsies in which they could demonstrate no lesions of the coronary arteries. Allbutt finds the supragsigmoid area of the aorta the seat of the disease. As to the cause of the pain, the intermittent claudication theory of Allen Burns seems to satisfy many competent observers. It may be defined as a state in which the artery admits enough blood for quiet work but not enough for increased work, and a heart the coronary arteries of which are sclerosed and non-elastic can well bring about this state. On the other hand, Mackenzie holds that the symptoms in all cases are due to exhaustion of the heart muscle; and if I may add my humble opinion, I believe that the type with the paroxysmal attacks of pain are due to some interference with the blood supply to the heart muscle,

while in the other type the symptoms are due to exhaustion of a *diseased* heart muscle.

TREATMENT

The treatment of the two types is different in some respects. Both types are benefited by prolonged rest, mental and physical relaxation, and reduced alimentation. The iodides seem to exert a beneficial influence given over a long period of time. The group of cases characterized by progressive myocardial exhaustion without pain are benefited more by digitalis than are those of the other group. It has been my habit to restrict the proteins somewhat in the type with paroxysmal pain, as well as to diminish the starches in the form of potatoes, bread and cereals. At the same time definitely diminishing the amount of food intake, while in the other group of cases it is usually better to allow a liberal protein diet. I am guided in this by the percentage of urea retained in the blood. The fluid intake allowed depends upon the tendency to edema. The abdominal symptoms are very difficult to relieve at first, but they clear up readily as the heart muscle regains its efficiency. The paroxysmal pain of the one group is usually promptly relieved by the nitrites, while the discomfort and abdominal symptoms of the other group are usually made worse by its use. The greatest difficulty is experienced in convincing the patient what his trouble really is. It is difficult to convince a patient that he must restrict his activities because of indefinite abdominal or gastric symptoms and that his life is in danger because he belches a little or suffers from abdominal gas.

RAILROAD SURGEONS CONDEMN ANTI-HEALTH AND ANTI-EDUCATION INITIATIVES

The following resolution was unanimously adopted by the Pacific Association of Railway Surgeons at their annual convention at San Francisco, August 26, 1922:

Whereas, There are three anti-health and anti-education initiatives before the people to be voted on at the general election, November 7, 1922, namely, the Chiropractic, Osteopathic and Anti-vivisection Initiatives; and,

Whereas, The three combined would permit the unqualified to practice unscientifically and prevent the qualified from practicing scientifically, by lowering educational standards, nullifying vital public health safeguards, making physicians and surgeons out of drugless practitioners with no proper preparation or experience; and,

Whereas, Educated physicians and surgeons would be "debarred forever" under the terms of one of these Initiatives, for daring to use a few guinea pigs to save the lives of countless people, be it.

Resolved, That this twentieth annual meeting of the Pacific Association of Railway Surgeons, in the interests of public health and safety and all whom we serve, do hereby condemn singly and collectively the Chiropractic, Osteopathic, Anti-vivisection Initiatives and urge all those interested in the scientific study, prevention, cure and control of diseases and the promotion of public health to vote against these dangerous measures.

THE GREAT SECOND TYPE OF CHRONIC ARTHRITIS.

By LEONARD W. ELY, M. D., San Francisco

THIRD STUDY
(Synopsis of Previous Work.)

In several previous articles I have attempted to demonstrate that all cases of chronic arthritis can be divided into two great types or groups differing markedly in their clinical appearance, and radically in their X-ray picture and their pathological characteristics. The first type includes the bacterial infections, and has for its pathological feature a proliferative inflammation in the bone marrow, in the synovial membrane, or in both.

The second type differs sharply from the first in almost every way, and has received many names based on features which their originators deemed important. Among these names may be mentioned arthritis deformans, osteoarthritis, hypertrophic arthritis, degenerative arthritis, metabolic arthritis, senile arthritis, destructive arthritis. The disease has been variously ascribed to trauma, loosely to infection and to some mysterious error in metabolism, some unknown chemical substance floating in the blood stream. I have shown that the disease could not be caused by trauma. The morbid changes in the joint are as different from those caused by bacteria as black is from white, and our efforts at Stanford to obtain bacterial cultures from the bone marrow and from the joint fluid have been uniformly unsuccessful. In such a situation the easiest way out is to take refuge in words, and to say that the disease must be due to metabolic error, to a dyscrasia, to a diathesis, to autointoxication from the colon, to a displaced vertebra or to an error of mortal mind.

This disease is characterized clinically by the presence of bony and cartilaginous ridges at or about the lines of attachment of the capsule, revealed by the Roentgen film. The surgeon who operates upon an affected joint makes his diagnosis upon this production of bone and cartilage, and the pathologist in the laboratory, recognizing the bone and cartilage changes, also bases his diagnosis upon them, and has always maintained that they were the characteristic and fundamental feature of the disease.

I have shown that the changes in the bone and in the cartilage were not primary but were the result of a previous aseptic necrosis in the marrow in the vicinity of the joint. This necrosis affects the bone and the marrow, giving rise to larger or smaller sequestra, and later to cysts, to bone cavities and to the so-called ostitis fibrosa. I have tried to establish the connection of this disease with fracture of the neck of the femur in the aged, and with the arthritis which follows an intra-articular fracture in an elderly person. The whole appearance of the lesion of the bone pointed strongly to a non-bacterial infection as the cause, but up to a few months ago I had never been able to discover any clue as to the nature of this organism.

In two previous papers I had called attention to the coincidence of infection in the alveolar proc-

esses of the jaws in patients suffering with this form of arthritis, and ascribed to this alveolar infection a direct and primary role in the causation.

This is as far as I had been able to go until this year. I quote from a paper prepared for presentation to this Society at its meeting last year, and published in the STATE JOURNAL: "No proof is at hand of the presence of infection in the bone marrow or in the joint fluid. Presumably the necrosis is due to a low-grade infection. In this case the organism itself must die out, or else is of such a nature as to escape detection with our present methods of examination."

WORK DURING THE PAST YEAR

The problem then narrowed itself down to this: What form of organism, not a bacterium, gains access to the circulation through the diseased bone at the roots of dead teeth, and, carried to the bone marrow, causes a necrosis, but never suppuration? Last autumn Dr. J. V. Barrow found the amoeba in the stools of one of my patients suffering with this form of arthritis, and I had the privilege shortly afterward of a long talk with him. Many observers hitherto have suggested a relationship between the amoeba and chronic arthritis, or chronic rheumatism as they were wont to call it. The point here was that the pathological lesion which I have demonstrated to be the primary and essential feature of this particular form of arthritis is exactly what one would expect if the amoeba gained access to the bone marrow. I am firmly convinced that a protozoön is responsible for the disease, as I should be sure of the presence of a gopher if I saw a small, peculiar pile of dirt in a field, and I should not be turned aside by anyone who ascribed it to planetary disturbances or to an excess of carbohydrates in the soil.

The next step was to find the amoeba, to dig up the gopher, so to speak. I recut my material, stained it with iron haematoxylin, and submitted sections of five joints to several authorities. Kofoid and Swezey maintain that they found amoebae in the marrow of one specimen. Their claim at present lacks confirmation, but it is suggestive and opens up an interesting field for investigation, a field which my associates, Doctors Reed and Wyckoff, are cultivating with me, assisted materially by Doctor Gunn. We realize that we have a hard task before us, but we propose to go to the bottom of the matter before we finish. Up to date we have found the amoeba in the stools of only two or three of our patients, as Doctor Reed will tell you.

As to the identity of the organism: I am not yet prepared to acquit the amoeba gingivalis of all blame, and to regard it as harmless in all circumstances, as do most authorities. It may be harmless at the roots of the teeth, but not harmless in the bone marrow. The almost invariable presence of alveolar infection in this disease is at least strong circumstantial evidence.

Kofoid and Swezey are fairly positive of their identification of the amoeba histolytica in one of my specimens, and ascribe the organism as occupying the exact situation which the nature of the fundamental lesion would indicate, namely, ranged along the finer capillaries of the marrow near the joint.

Concerning the symptomatology and pathology I have nothing to add to the descriptions in my two earlier studies. As to treatment: The first indication is to remove the infection about the roots of the teeth—to close the portal of entry, so to speak. Extraction is the only rational procedure, in my opinion. My experience with the so-called radical operation, that by chiselling away the alveolar process, and cleaning out the suppurating osteomyelitis is not such as make me eager to recommend it to others. Simple extraction gives the best results.

The next step in the treatment is to search for amoebae in the stools of the patient, and to eradicate them by some preparation of ipecac if they be present.

In certain cases, in which the pain continues after the removal of the focus of infection in the jaws, the injection of a foreign proteid intramuscularly may be of service. In this connection it should be remembered that when a joint is badly damaged mechanically by the disease, the pain and discomfort felt when it is used may persist, even when the active disease has subsided.

Hydrotherapy and dry heat will also be found of help to quiet the pain. In the severe cases of this form of arthritis, occurring in a single joint, as in the knee, or especially in the hip, a resection often offers the best way out.

Most cases of brachial neuritis, myositis, fibrositis, radiculitis, lumbago and sciatica, will on examination be found due to a spinal arthritis and will improve under treatment along the lines I have indicated.

NEW CASES

Following is a tabulation or seventy-three new cases seen at the Stanford Clinic during the past year. In numbers, and in almost every way, they run about parallel to the two preceding series. The presence of alveolar infection is determined almost invariably by our dentist, Dr. Campbell, with the X-ray.

Fifty-six of the patients were men, seventeen were women. The youngest was 27 years old, the eldest 87. One patient was in the third decade of life, sixteen in the fourth, seventeen in the fifth, sixteen in the sixth, eighteen in the seventh, five in the eighth, and one in the ninth. Alveolar infection was present in fifty-two patients, probably present in eleven patients. Five of these latter did not have radiograms taken. In one patient the question of alveolar infection was not determined. All teeth were gone from the mouths of eight patients. This is prima facie evidence of previous infection. Alveolar infection was absent in only one case.

The analogy of the cases in this series with those in the two preceding is so close that the disease might almost be charted with regular curves. Basing the statement upon clinical and laboratory work I think we are now justified in laying down the following description:

The great second type of chronic arthritis is

probably caused by a protozoön which almost invariably gains access to the system through the diseased bone at the roots of decayed teeth. Its prime pathological characteristic is an aseptic necrosis in the marrow in the immediate vicinity of the joint, and it is recognized radiographically by the presence of the spurring and lipping at the lines of attachment of the capsule. It is about twice as frequent in men as in women as clinically observed. It is distinctly a disease of middle and late life, and never occurs before the third decade. Up to date the best results in treatment have been obtained by the removal of the focus in the alveolar process of the jaws.

No.	Age	Sex	Occupation	Joints Involved	Alveolar Infection
153	45	F.	Housewife	Knees	Present
154	33	M.	Laborer	Tarsus	Present (Complete recovery)
155	58	M.	Baker	Hip Old healed fracture of neck	Present
156	33	M.	Glasshouse factory worker	Spine	Probably present. Would not have teeth X-rayed
157	45	M.	Laborer	Spine	Present
158	67	M.	Laborer	Spine	Present
159	36	M.	Laborer	Spine	Probably present
160	48	F.	Student	Knees	Not determined
161	64	M.	Laborer	Knee	All teeth removed 20 years previously
162	62	M.	Laborer	Spine	Present
163	56	F.	Housewife	Shoulder and knee	Present
164	34	M.	Laborer	Spine	Present (probably)
165	43	M.	Laborer	Spine	Present
166	52	M.	Carpenter	Spine	Present
167	42	M.	Laborer	Spine	Present
168	52	F.	Domestic	Hands	All teeth gone
169	52	M.	Barber	Spine	Probably present
170	73	M.	Janitor	Knees	Present
171	55	M.	Laborer	Knee	Probably present
172	35	F.	Housework	Sacro-iliac	Present
173	35	M.	Laborer	Spine	Present
174	61	M.	Tinsmith	Spine	Present
175	65	F.	Housewife	Knees	Present
176	50	M.	Laborer	Spine	Present
177	67	M.	Salesman	Spine	All teeth gone
178	78	F.	Housework	Knee	Present
179	57	F.	Housework	Knees	Present
180	48	F.	Housewife	Knees	All teeth had been removed for decay
181	56	M.	Motorman	Spine	Not determined by X-ray. Teeth suspicious
182	63	M.	Lumberjaek	Spine	Apparently present about few remaining teeth. No X-ray taken
183	40	M.	Laborer	Spine	Apparently present. No X-ray taken
184	53	F.	Housework	Knee	Present
185	67	M.	Railroad worker	Multiple	Present
186	27	F.	Domestic	Spine	Present
187	46	F.	Dressmaker	Knee	Present
188	48	F.	Laundry work	Knees and feet	Present
189	48	M.	Laborer	Spine	Present
190	66	M.	Laborer	Knee	Present
191	67	M.	Laborer	Spine	Probably present. No X-ray taken
192	52	M.	Seaman	Spine	Present
193	66	M.	Laborer	Spine	Present
194	65	M.	Laborer	Spine	Present
195	42	M.	Carenter	Spine	Present
196	63	M.	Laborer	Wrist	Present
197	70	M.	Stonemason	Spine and aeromioelavicular	Present
198	52	M.	Tailor	Spine	Present
199	60	M.	Laborer	Multiple	Present
200	46	M.	Expressman	Spine	Probably present
201	48	M.	Laborer	Spine	Present
202	36	F.	Officeworker	Spine	Present
203	56	M.	Blacksmith	Spine	Present
204	34	M.	Waiter	Spine	Present
205	75	M.	Watchman	Spine and shoulder	Present
206	49	M.	Houseman	Spine	Present
207	39	M.	Stevedore	Spine	Present
208	49	M.	Laborer	Spine	Present
209	67	M.	Glazier	Shoulder and aeromioelavicular	All teeth gone
210	50	M.	Packinghouse worker	Hips	Absent
211	63	M.	Cook	Spine	Present
212	54	M.	Laborer	Spine and shoulder Dupuytren's contraction!	Present
213	76	M.	Laborer	Spine	All teeth gone
214	35	M.	Laundry worker	Spine	Probably present. No X-rays
215	35	M.	Laborer	Spine	Present
216	61	M.	Solicitor	Spine	Present
217	32	F.	Housewife	Knee	All teeth gone
218	60	M.	Cook	Spine and feet	Present
219	43	M.	Laborer	Knee	Present (Note—Amoeba found in stools)
220	46	F.	Housewife	Spine	Present
221	39	M.	Salesman	Spine	Present
222	38	M.	Laborer	Spine	Present
223	63	M.	Driver	Knee	Present
224	87	M.	Ex-miner	Spine and knee	Edentulous
225	37	F.	Stenograher	Spine	Present

MEASUREMENTS BASED UPON ROENTGEN EXAMINATION OF ONE HUNDRED NORMAL CHILDREN.*

By ELISABETH SCHULZE, M. D.
(From Department of Roentgenology, University of California Medical School)

Much has been written about the pituitary and its normal function in growth and development, as well as about disorders arising from disturbed function. Aside from the changes and symptoms to which these disorders lead in accessible parts of the body the most direct method of approach to investigation on the living subject is the X-ray study of the size and shape of the sella turcica. Various investigators, undertaking to define the normal latitude of variation in the size and shape of the sella, have come to the conclusion that there is a wide range of variability in individuals presenting no evidence of pituitary dysfunction clinically. Others have found that cases with fairly marked clinical evidence of dysfunction may occur which do not present any deviation from the normal limits, as far as the size and shape of the sella is concerned.

Recently A. J. Pacini, in attacking this problem, has called attention to an angle at the base of the skull, the so-called sphenoidal angle of Welcker; and to the possible relation of the size of this angle and the type of sella accompanying it, to pituitary functional disturbances which could not be determined by study of the sella alone. The angle, originally described by Virchow many years ago, and then studied by Welcker and Broca, and concerning which very little has since been contributed, lies between two lines in the central sagittal plane of the skull. One line extends from the nasion, or anterior central point of the fronto-nasal suture, to the turcicon, or the middle point of the sella; the other extends thence to the basion, or anterior point of the rim of the foramen magnum. In making his studies Pacini chose instead of this angle, another, which is a little more easily laid out on the X-ray plate, namely, the angle between the lines, one, as above, running from the nasion to the turcicon, but the other running thence to the akousticon, or uppermost point of the external auditory meatus shadow, instead of to the basion. This angle, he maintains, is directly analogous to the original sphenoidal angle of Virchow and Welcker. Although there are a number of statements in the body of the paper and in the conclusions, which, probably owing to typographical error, are directly contradictory to each other, I believe that the impressions which he wished to express are as follows: The angle of Welcker, which normally is flattest in infants, becomes progressively more acute in the child, the woman, and the man (representing progressive stages in skull evolution). With this progressive narrowing of the angle, the sella, which in a measure surrounds the apex of the angle, is opened up so that the clinoid processes diverge more and more and the volume of the pituitary increases. In other words an obtuse angle and a closed sella (apparently meaning one in which the clinoid processes seem to closely approach each other or to overlap on the X-ray plate) are characteristic of the child and woman, while a more acute angle and an open sella are characteristic of man. If pituitary function becomes abnormal before skeletal growth is complete this relationship may be disturbed. Thus, a female type of angle (obtuse) may be accompanied by an open sella, indicating hyperpituitarism, or a male type of angle (more acute) may have a closed sella, indicating hypopituitarism. Other similar points are brought out. The average measurement of the angle (for adults) is 135 degrees; females should range above this and males below, the extremes being 160 degrees in a woman and 110 in a man. Children would presumably range from very high to the average reading, according to their ages.

In order to verify, if possible, some of these statements, and also to bring out new points of interest, one hundred normal children fairly evenly distributed as to age from three to sixteen years, were studied. There were about equal numbers of the two sexes. Among these children there were many groups of brothers and sisters. Careful measurements of the height (standing and stem-length) and the weight were made, as well as a rough estimate of the intelligence. Most of the children conformed to the limits of the averages determined for these measurements by Burke and others from very extensive material. A number, while a little above or below the average, were still within the normal limits of individual variation. The intelligence varied from very bright to dull, without any distinctly abnormal cases.

X-rays were taken of the hands and wrists to study centers of ossification, etc.; and of the skull, an attempt being made to get an absolutely true lateral of the sella in every case, but here considerable difficulty was encountered. Pacini's technique, as described, if accurately followed, gives a true lateral, but the least deviation (which is hard to avoid unless the greatest care is exercised) causes a wide variation in the measurement of the angle he describes, that is, if one takes into account only the external auditory meatus of the side next to the plate. Pacini makes no mention of using both. However, if the angles to both meati are measured and the reading midway between the two is taken, it remains quite constant for any reasonable deviation on a lateral plate, and measures the same as that obtained by very accurate technique. It does not make any difference which side of the head is next to the plate, although Pacini laid great stress on this point. These points were very clearly demonstrated by taking pictures of a skull in which the angles themselves were actually outlined with wires, also by checking these findings on numerous living subjects.

When the angle was measured by the Pacini method it was found to range from about 140 to 165 degrees in these normal children, the average being 151 degrees, and there being no appreciable average difference between the younger and the older children, nor in the heavy and light weight, nor in the tall and the short.

* Read before the Section on Radiology of the California Medical Association in Yosemite National Park, May 18, 1922.

Thinking that perhaps more acute angles would be found in adults, one hundred normal cases were measured, about equal numbers of males and females, and the range in males was found to be from 135 to 165 degrees with an average of 149 degrees, while in females it was from 138 to 160 degrees with an average of 147 degrees, in other words so slight a difference as to be of no practical importance. A few cases of hyper and hypofunction of the pituitary with and without recognizable sellar changes were also measured and gave no different or distinctive findings. As one may readily note, these figures are much higher than those given by Pacini. The only way I can account for the discrepancy is that Pacini perhaps measured from one meatus only and so may not have gotten the true value of the angle, or that he had a different type of patients, which does not seem very probable since a number of nationalities were included in our series, and no constant difference was noted.

Concerning the width of the space between the anterior and posterior clinoid shadows, which Pacini lays stress on, nothing characteristic could be made out. There was a wide variation without particular relation to age, sex, or size of the sphenoidal angle. With the general increase in the size of the skull the sella increases in size also.

Finding these results rather ungratifying, an attempt was made to mark out the true sphenoidal angle of Welcker on the plates and to see if anything could be gained by a study of it. We found that after it had been mapped out by wires on a dry skull and then located in Roentgenograms of this, it was also fairly easily located on plates of the living subject, and in no case did the angle as measured vary more than three or four degrees in different pictures of the same subject. The measurements thus obtained conformed much more closely to those given by the old anthropologists for this angle. Welcker gives a table in which, from the measurement of eight infants, he obtained an average of 141 degrees, from ten children 137 degrees, and from thirty adults 134 degrees. While these figures were obtained from accurate measurements on the skull, the difference is so slight that it would be difficult to check on X-ray plates, since it is almost within the limits of error by this method. The measurements actually obtained from X-rays varied from 122 to 142 degrees, running slightly higher in the younger than the older groups, the general average being about 133 degrees.

Aside from this matter of sphenoidal angles a few other points of interest were noted.

Tracings were made of the size and shape of the sella as shown on the X-ray plates and a definite resemblance in the size and conformity of the sella in individuals belonging to the same families was noted. About twenty-five family groups of two to five children were studied. No reference to this observation could be found in the literature, although Schuller has called attention to the fact that there is a family resemblance in the shape of the bones of the head, and that this accounts as much or more than the configuration of the soft parts in bringing about a similarity of features.

A slightly calcified pineal, verified by another plate, was found in a girl of thirteen years, seven months, apparently normal.

The time of appearance of centers of ossification in the wrists and of epiphyses showed a wide variation and was not always the same for the two wrists of the same individual.

CONCLUSIONS

The angle of Pacini was not found to be analogous to the sphenoidal angle of Welcker, nor could his measurements for his angle be confirmed.

There is a definite family resemblance in the size and shape of the sella.

I wish to express my apreciation of the valuable advice and aid of Dr. H. E. Ruggles in the preparation of this work. He has suggested other measurements, such as the ratio of the distance from the naison to turcicon, to the distance of the point of the chin from the turcicon, which give promise of being much greater value and which will be the basis of a later report.

ABOUT BIRTH CONTROL

Whatever else one may think about birth control and methods for making it effective, the much expressed modernity of the idea is probably about as accurately stated as are many other so-called "scientific facts." Adolph Koenig (Pennsylvania Medical Journal, August, 1922), calls attention to Elegy XIV, Book II, Ovid, written about the time of the birth of Christ, a translated quotation of which is interesting and instructive:

"Because thy belly should rough wrinkles lack,
Wilt thou thy womb-enclosed offspring wrack?
Had ancient mothers this vile custom cherished,
All humankind by their default had perished;
Or stones, our stock's original, should be hurled
Again, by some, in this unpeopled world.
Who should have Priam's wealthy substance won,
If watery Thetis had her child fordone?
In swelling womb her twins had Ilia killed,
He had not been that conquering Rome bid build.
Had Venus spoiled her belly's Trojan fruit,
The Earth of Caesars had been destitute.
Thou also, that wert born fair, had'st decayed,
If such a work your mother had essayed.
Myself, that better die with loving may,
Had seen, my mother killing me, no day.
Why tak'st increasing grapes from vine trees full?
With cruel hands why dost green apples pull?
Fruits ripe will fall; let springing things increase;
Life is no light price of a small surcease.
Why with hid irons are your bowels torn?
And why dire poison give your babes unborn?
At Colchis, stained with children's blood, men rail,
And mother-murdered Itys they bewail.
Both unkind parents; but, for causes sad,
Their wedlocks' pledges venged their husbands' bad.
What Tereus, what Jason you provoke,
To plague your bodies with such harmful strokes?
Armenian tigers never did so ill,
Nor dares the lioness her young whelps kill.
But tender damsels do it, though with pain;
Oft dies she who her paunch-wrapped child hath slain;
She dies, and with loose hairs to grave is sent.
And whoe'er see her worthily lament.
But in the air let these words come to naught,
And my presages of no weight be thought.
Forgive her, gracious gods, this one delict,
And on the next fault punishment inflict."

CLINICAL MISTAKES IN GYNECOLOGIC DIAGNOSIS*

ROLAND E. SKEEL, M. D., Los Angeles.

Science is defined as exact classified knowledge, and art as the application of scientific principles. It is with the conviction that we are losing much in the Art of Medicine through focusing too strongly on the results of the tremendous development of medical science that this short paper is presented for discussion, and to this end, gynecologic diagnosis has been selected in preference to the diagnosis of other abdominal and pelvic diseases, because the most vivid illustrations of the type of mistake which we have in mind are found in the former.

Similar mistakes in diagnosis and in treatment, based upon an erroneous assumption of the relation between the disease process and the symptoms presented, are to be found when the stomach, gall bladder, appendix or colon are suspected, but for various reasons these are not so common as in the gynecologic field.

It is perhaps true that gynecologic diagnosis is less susceptible of pre-operative laboratory confirmation than the others mentioned, but ocular inspection and bi-manual palpation give such direct access to the female pelvic organs that gross mistakes as to the pathologic condition are relatively infrequent. Such as do occur may often be laid to an incorrect history given by the patient, who denies a previous pregnancy, deliberately lies about her menstrual history, or consciously or unconsciously denies all symptoms pointing to an old gonorrheal infection.

At other times inadequate examination or imperfect knowledge leads to the treatment of pruritus vulvae without examination of the urine, the assumption that leucorrhea is due to chronic corporeal endometritis or that intermenstrual spotting is of no particular significance. These are matters of common elementary knowledge and do not come within the scope of the present discussion.

It is a less tangible subject that we wish to discuss, viz., our mistakes in diagnosing the relationship between the objective signs of disease or abnormality and the subjective symptoms of which the patient complains, and the best line of approach may be to question why patients consult the physician, and how pelvic abnormalities happen to be discovered.

It is evident that the routine physical examination to which the general physician, general surgeon, urologist or gynecologist submits his patient may bring these to light, and a correct estimate of their bearing upon the patient's subjective symptoms is of great importance if she is to be relieved of her discomfort.

On the other hand, the patient may present herself because of some obvious physical sign such as an enlarging abdomen, a protruding mass at the vulva, or a vaginal discharge, or she may be the victim of local pain which she attributes to disease of her generative organs.

On his part the examiner may discover a lesion, like early cancer of the cervix or true ovarian cystadenoma, which, left to itself, is necessarily fatal, and in such an event his course is plain, regardless of the character of the subjective symptoms or even their entire absence.

He may discover other lesions, such as prolapsus uteri, symptomless fibroids, pyosalpinx, or gonorrheal endo-cervicitis, none of which necessarily or even frequently jeopardizes life, but any of which do endanger the future health; or he may find any one of an array of minor deviations from the normal, and associated with them a great variety of symptoms, pelvic pain, backache, headache, dysmenorrhea, "nervousness," etc., which may be, but more frequently are not, in any way referable to the pelvic lesion which the examination reveals.

It has been considered axiomatic that successful treatment depends upon a correct diagnosis, but we hold it more nearly true that successful treatment depends upon that accuracy of prognosis which follows a *complete* diagnosis. Thus the treatment for carcinoma of the cervix is dependent upon the stage which the disease has reached when the diagnosis is made, rather than the fact that cancer exists. Opinions might differ as to whether an individual patient should be operated upon, be subjected to radio-therapy, or left without radical treatment, all in accordance with the knowledge and previous experience of the physician consulted, but the ultimate factor governing his advice would be an estimate of the prognosis either with or without treatment, so that an absolute mistake in diagnosis might be of no more serious import to the patient than an imperfect opinion of the outcome under any one of the various forms of treatment possible. However, in such a necessarily fatal disease the subjective symptoms of the patient are of no consequence; it is the disease only which counts, and symptoms can be ignored.

It is somewhat different in those pelvic disorders which infrequently jeopardize life but do menace the health, and it demands a most thorough and accurate study of the patient as a whole to be able to make a complete diagnosis and suggest the line of treatment to pursue. Two patients recently have come under my observation who illustrate the damage which follows hasty, ill-advised or illogical treatment. One woman of thirty had suffered a panhysterectomy five years previously for no better reason than that a deep laceration of the cervix might lead to cancer, and another of sixty submitted to a hysterectomy for a symptomless fibroid nodule no larger than a cherry. A third patient died in consequence of an operation for peritoneal adhesions which, even though they existed, were symptomless.

All of these reveal a correct pathologic diagnosis, but an utterly false clinical diagnosis, which was based upon an erroneous conception of the prognosis of cervical lacerations, uterine fibroids and intra-peritoneal adhesions per se. All of these are potentially serious, but under the circumstances, and with no symptoms that would justify interference, not one approached in gravity the operation which was performed for its relief.

* Read before the Section on Obstetrics and Gynecology of the Medical Society of California at Yosemite National Park May 15, 1922.

Aside from the injustice of major operations for minor difficulties another phase must be taken into consideration. Without a doubt more than one patient with a similar lesion was likewise advised that an operation was necessary, refused surgical interference, and has continued to live a comfortable, happy life under the guidance of one of the devotees of the anti-medical cults, to the discredit of medicine as a whole and surgery in particular. Now neither medicine nor surgery has reached the accuracy of deduction of an exact science, and human fallibility alone is productive of enough legitimate errors in diagnosis and prognosis without having our art overloaded by clinical mistakes of this particular type.

If care is necessary in order to avoid these mistakes, it is even more so in such conditions as minor injuries to the pelvic floor, ordinary cervical lacerations in young women, and the whole gamut of malpositions of the uterus. A great number of malpositions associated with pelvic discomfort, backache, dysmenorrhea, and irregular menstruation, occur in women whose bodily form and mental reactions point unerringly to poor development, while in others the symptomatology presented is so inconsistent and broadcast, as it were, as to make it apparent at first sight that the trifling gynecologic lesion means nothing more than that such lesion happens to be present in a psychasthenic or neurasthenic woman. Picking the history apart and delving into the private lives of these individuals is much more likely to give a clue to the proper treatment than jumping to the conclusion that the pelvic abnormality is responsible for the symptoms, and proceeding at once to dilate the cervix or shorten the round ligaments.

It is not intended to convey the opinion that a cervix never requires dilatation or a uterus reposition and support. If a cervix does require dilatation it is because the symptoms which exist are unequivocally those of obstruction, and if temporary replacement of a retroverted uterus overcomes the patient's local discomfort so definitely that the result cannot be attributed to mental suggestion, that uterus should be provided with some form of permanent support.

Local treatment for its suggestive effect may on occasions be perfectly legitimate, but as a general rule the result of fixing an abnormally introspective mind on a reasonably healthy set of pelvic organs is so disastrous that it should be undertaken with the greatest circumspection.

Honest mistakes of the kind we are discussing seem to me to arise from a number of sources and to be avoidable to a great extent. Many of them, no doubt, are an inheritance from the days when gynecology was in its infancy and a woman was regarded as only "an organism around a womb." Others arise from the fact that so many superficially educated, so-called cultured, people are entirely devoid of a commonsense knowledge of their bodies, and are superstitious to the last degree concerning them. Even in this advanced scientific age many are not willing to grant us as much time to investigate the extremely complicated human machine as they would give a garage mechanic to find why their motor had ceased to function. On our side we dislike having even the stupidest patient think we are less smart than our colleague whom they will consult when convinced that care in arriving at conclusions on our part means incompetence — hence we make a snap diagnosis.

Among the minor matters that contribute to our failure accurately to estimate the factors (the so-called imponderables) we cannot fathom by our senses and instruments of precision, is the necessary one of history taking. I defy the man who asks questions and writes, writes and asks questions, to show as broad an insight into the patient's condition as the one who merely asks his questions without writing. This may seem trivial, but it has appealed so strongly to me that in any obscure case, if I must take the history myself the diagnosis is deferred to a later date, when I can refer to the history, and quiz without writing.

Intensive and narrow specialism is another reason for these clinical mistakes. *Specialism* is responsible for many of the most important advances in medical knowledge, but *specialists* are unsafe guides unless they have the proper fundamental groundwork, and a broad experience in medicine and surgery as a whole. The ideal specialist is said to be one who knows as much about every part of the body as any one, and more about that in which he specializes. This ideal of course is impossible of attainment, but I am inclined to think that it is most nearly approached by one who is driven into his line of work by an unconscious fitness which makes him study his subject until he knows it so well that his colleagues give him no time to practice anything else.

In any event, such a specialist is not likely to attribute occipital headache to a prolapsed ovary, left-sided inframammary pain to salpingitis, or a burning sensation in the abdomen to endometritis.

Last, I think many of our mistakes in this field have arisen because of the enormous strides made in laboratory diagnosis. Both in this and the preceding subject of specialism, the complaint is, not that they themselves are deserving of criticism, but that certain undesirable by-products have been thrown off during their generation and development. The laboratory does not concern itself with individuals but with fluids and tissues, their abnormality or otherwise. It is concerned with material and physical findings, not with the reactions of the brain to the multiplicity of sensations which reach it from all the sense organs and sensory endings in the body. Hence while the laboratory is a guide to the diagnosis of disease, it is of little or no assistance in explaining the symptoms produced by disease, or the symptoms which may exist entirely independent of any disease diagnosable by laboratory methods.

It may be sufficiently accurate to consider one gynecologic patient as a *case* of gonorrhea, another as a *case* of cancer, and still another as a *case* of ovarian tumor, because in these the pathologic process mentioned is the predominant factor. It is, however, a gross mistake to attempt to solve the trouble equation by the same formula when an unmarried woman, below weight, with a long, narrow thorax and descent of all her abdominal

viscera, presents herself with spasmodic dysmenorrhea and is found to have a small ante-flexed uterus; or, when the woman of thirty, who has suddenly grown stout, wishes to know why her menses are irregularly late and scanty, and her uterus is discovered to be atrophic.

These are not *cases* of uterine anteflexion, infantile uterus, or hyper-involution; in fact, they are not gynecologic cases of any sort, but purely the local results, one of general maldevelopment, the other of thyroid dysfunction.

One might mention patients of another type like the multipara who has borne and nursed three or four children in as many years, who has small cervical and perineal lacerations, and complains of backache and general weakness, who is not a *case* of lacerations but a woman who has been chained to her domestic duties, has exhausted herself by attention to her children, and has a holy and well-grounded fear that respect for her contracted marital relations will lead to more babies, more work, more nursing and more expense. Repair of her injuries may help her temporarily because she is given a cathartic, put to bed and subjected to an entire change of surroundings, but the treatment is based upon an erroneous diagnosis nevertheless.

What we have been endeavoring to arrive at is difficult to put in words both exactly and precisely, but perhaps we can best summarize it by repeating that there are a very limited number of gynecologic diseases in which the pathologic and clinical diagnoses run parallel, and in them we make but few mistakes. These are exemplified by carcinoma of the uterus and ovarian cystadenoma.

There are a number of others in which the pathologic process is plain, but its effect upon the patient's present or future health much less certain, and in their presence we blunder unless the relation is most carefully considered; and there are a host of minor deviations from the normal in which the relation between the trivial pelvic pathology and the patient's symptoms are problematic to say the least, and in which treatment based on gynecologic diagnosis more often fails than otherwise, because we focus our attention upon the disease and completely overlook the patient.

There is a medical science and a science of medicine, but as yet very little exact classified knowledge of symptomatology; hence our gross mistakes when we operate for pathology and overlook the patient, mistakes which the cults who cannot operate never make, therefore their widespread popularity among those who are looking for relief from their discomfort and care not at all if they are carrying some organ whose condition or position does not conform to our ideals of a theoretic normal.

DISCUSSION

James Percy, San Diego—I only want to discuss one phase of Dr. Skeel's paper and I am so glad he touched upon it because it is the phase that pertains to not only the gynecological practice but all types of practice. One fact so often overlooked in the practice of medicine is the neurological side, the functional side of our patients. I presume it is true that 75 per cent of the women, speaking of them now only, that come into the doctor's office, are so-called neurotics, and unfortunately, I don't care in what specialty it is, the specialist whose office that particular woman goes into is almost bound to do only for her the thing that he has developed and that he knows as his specialty. In other words, the patient as an individual is entirely overlooked, a point so well brought out by Dr. Skeel when he used that phrase "narrow specialism." I don't want to think that any of us are dishonest, but I sometimes see things that make me wonder if we are dishonest, but I think we are either dishonest or grossly ignorant. If we are ignorant in medicine, then we are dishonest. Just think of the number of women who are operated upon and promised relief from some minor things, as the essayist brought out, and then are turned loose and do fine for a couple of weeks while they are wearing out the experience they have had incident to the rest in the hospital, and later come back with all the old symptoms. The next thing we hear is that they have gone to someone else and gotten into the hands of some other specialist and the same thing is repeated.

It is essential to inquire into the early history because of its importance in bringing out the underlying factors of the malady. It is so easy for us to ask questions on the matters that we are most interested in and leave out everything else.

Recently I saw one of the most beautiful records of a highly trained gastro-enterologist. It was a work of art and he wrote it himself on the typewriter, things emphasized with red ink and yet no one had looked into the patient's mouth. You could move every tooth, they were all dripping with pus.

I never believe any word that any patient tells me in describing certain symptoms until I can absolutely convince myself that she is telling the truth because I have seen too many of these women cured by the osteopath, when, in fact, the neurotic element was the sole pathology.

There is little to say in closing; but, like Dr. Percy, I have been tremendously impressed, especially since coming out here, with the danger which the whole medical profession is resting under. I know it is not so grave in the East, but even there the risk it is running from the incursions of every variety of cult is apparent. The strenuous struggle which the profession here is making to keep its head above water has also impressed me, but it is apparent that the profession itself is to blame for many of the evils with which it is confronted. We fail in our methods of handling these minor disorders and swell up with pride over a hysterectomy or some other spectacular operation, but completely forget about the half dozen or so women on whom we have done a curettage or repair of the cervix who return with exactly the same complaints as before. Objectively they may be well, but subjectively they are just where they were before we operated; hence this plea for more accurate clinical diagnosis.

The Difference—Physicians are often criticized for not taking their patients into their confidence, while it is stated that the popularity of the chiropractor is due to his perfect frankness in this regard; from which it would appear that the difference between the physician and chiropractor is that the physician knows what is wrong with the patient but won't tell, while the chiropractor doesn't know what is wrong, but is glad to tell it.—Bulletin of Cleveland Academy of Medicine.

THE MODERN TREATMENT OF THE WEAK OR FLAT-FOOT*

By G. J. McCHESNEY, San Francisco

The subject of arch strain is old and trite, and consequently neglected far too much nowadays in orthopedic literature. With the exception of an article on felt arch supports in the last number of the Journal of Bone and Joint Diseases there has been nothing for a year at least. And this is not because cases of arch strain are becoming infrequent. In the practice of most orthopedic surgeons, as well as in my own, the problem of arch strain and arch support is twenty-five to fifty per cent of the total. Neither does this scarcity of the literature mean that the profession is a unit as regards methods of procedure. The varying types of metal arch supports, as well as those of leather, felt, or what not, compete for our favor with various modifications of heels, shoes, etc. The patient, as a result, goes from one to another device with little satisfaction or relief.

My excuse for reading this paper is to present a plea for a return to physiological and natural methods of treatment. Simplicity is allied to efficiency, but this is too often lost sight of in treating the pronated or weak foot. The symptoms of these conditions are too familiar to require repetition, but let us review facts concerning the anatomy which we all know very well but too often fail to keep in mind.

The internal longitudinal arch of the foot is composed of the inner three metatarsal bones, the three cuneiform bones, the scaphoid, astragalus and os calcis. They are so arranged as to form a curve convexity upward, and highest on the inner side. The summit of this arch or dome is formed by the head of the astragalus, resting upon the calcaneo-scaphoid ligament. This ligament is also called the spring ligament, on account of its numerous elastic fibres, and here lies the burden of my song. The function of the internal longitudinal arch is primarily that of a spring to provide spring and elasticity to the gait, to ease the jar of the impact of the body weight against the ground, but not to bear the whole body weight all the time. The arch, then, is a spring in its action, is the shape of a long automobile spring, and when causing pain due to overstrain from overweighting, should be treated along mechanical rules applied in treating overweighted springs, and nothing else. Does a mechanic in treating a weak or overstrained auto spring put a prop or support in its middle? This would be foolish, for thereby all spring action or function would be nullified. The same rule applies to our use of so-called arch supports. They destroy the spring action of the arch and hence their use is inherently vicious, as no part of our body can be considered as healthy if not performing the function for which Nature intended it. In addition, a deleterious pressure is exerted upon the short flexor muscles and plantar fascia, and causes a pressure atrophy of these structures which retards a return to normal function after this pressure is removed.

The other well-known disadvantage of arch supports I'll not dwell upon—their cumbersomeness, weight, cutting of shoes, etc.

If, then, we should not support our arches by a central prop, what is best to do? To return to our mechanical engineering simile, the first measure is to remove our load or a large part of it; the second is to strengthen the elements of the arch itself, not prop it up. To remove the load, I insist on two things, first, proper posture; second, raised inner sides of shoes. In almost all cases of arch strain, the line of weight passes down the tibiae to the inner sides of the feet. Usually it can be demonstrated to the patient standing, and also to the friends or relatives observing from the rear, that the line of weight passes down to the inner side of the everted os calcis. If the os calcis is everted, the rest of the foot is everted, as it is an axiom in orthopedics that the way the os calcis goes the rest of the foot goes. This, then, means that the greater part of the body weight is upon the inner side of the foot, or the internal longitudinal arch, instead of upon the external longitudinal arch or outer side of the foot, which is almost flat, and is intended to bear the bulk of the weight, leaving the internal longitudinal arch free for its function of a spring. This latter result can be partially brought about by insisting upon the proper posture, i. e. by standing and walking with the feet parallel and not toed out, Charlie Chaplin style, as we have been taught to do by our mothers, teachers, dancing-school teachers, military instructors, etc., from time immemorial. In addition, high-laced shoes, not Oxfords, with the inner sides of soles and heels raised one-quarter inch in average, and three-eighths of an inch in severe cases, are ordered. It is my practice to measure and inspect these alterations myself before the shoes are worn, as cobblers are careless and have to be checked up at all times. The shoes are then tried on and the line of weight-bearing through the foot to the ground again noted, especially from the rear through the os calcis.

These simple measures are usually sufficient to remove the principal load from the overstrained arch. The fault has often been committed of not building up the shoes enough. Very rarely is one-eighth of an inch raise enough. I find one-quarter inch not too much even for children where it is a routine measure, and three-eighths is often necessary in severe cases in adults. Some strain of the peroneal tendons or the external lateral ligament of the ankle-joint may be felt for a few days, but soon disappears. It rarely requires adhesive strapping.

The second mechanical or engineering measure employed is the strengthening of the arch components; which here means exercise to strengthen the muscles and ligaments that hold up the arch. The following are two simple exercises: First, inverting the feet while standing, or balancing upon the outer edges of the feet; and second, rising upon the toes and then slowly coming down upon the outer edges of the feet to the outer edges of the heels. These exercises should be done as often as possible or practicable, and it is always emphasized

* Read before the Section on Orthopedic Surgery of the California Medical Association in Yosemite National Park, May 17, 1922.

that upon the faithfulness with which these exercises are done depends the speed of the cure and the cessation of the need for building up the shoes. There are no new features about these exercises. They are designed, of course, to strengthen principally the Tibialis Anticus and Posticus muscles, which we must agree are the ones principally involved, especially the latter, which exerts a direct upward pull upon the head of the astragalus. As the muscles of the foot are designed to do their principal work while the individual is walking or standing, exercises are of the most value while in the weight-bearing position, and exercises while sitting do not give the arch-supporting muscles enough to do. This is an important point, and explains why exercises while sitting often do little good and, in fact, may tire the legs excessively from the unnatural work the muscles are called upon to do.

With these simple measures immediate relief is afforded to all but the most acute cases of arch strain, and these are really better off in bed till the acute symptoms subside. Arch supports may get them up a little sooner, but far from cured. In fact, the chief mistake in the use of plates, aside from the using of them at all, is the wearing of them far too long. Instead of being provided as a very temporary appliance and to be supplanted by other measures as soon as possible, they are put on as a permanent curative device and no time limit set upon their use. Consequently very soon the patient finds out for himself that he is just as comfortable without arch supports as with them, and not really comfortable in either case—hence not cured.

The softer the material used, the less the discomfort and damage to the arch-supporting structures, but the same inherent objection applies to all, i. e. they do not tend to restore to the arch its proper function, that of a spring. Hence they are not a bit curative and only sometimes palliative.

I have found that this method of treatment applies to the very young as well as to the adult, but sometimes the advanced in years, with arthritis, will not tolerate a changed line of weight-bearing and are better off with soft pads under the arch to distribute the weight on the tender feet, and any idea of restoring the spring action of the arch hardly advisable on account of the age of the patient.

In injuries to the feet especially it is important to strive at all times for a restoration of proper function. In Potts fracture especially, and in all non-ankylosing fractures about the ankle-joint or in the tarsus, the foot should be put up in supination in the splint; that is, in the very position I have been trying to prove is the best one for a weak foot. When the splint is removed, why put a hard metal support under the tenderest and weakest part of the foot, with no provision for removing most of the weight by simply continuing the supinated position in shoes built up usually three-eighths of an inch? The fear that the arch will be strained if no support is put under it is quite groundless if this simple precaution is taken, supplemented, of course, by voluntary exercises along the lines previously described.

In all foot and ankle fractures, where no ankylosis is a result, I have obtained very easily return of function by these measures, and if in these very exaggerated cases of weak foot no so-called arch-supports are needed, why should they be needed in the milder, non-traumatic cases, even though of longer duration?

Of course, cases with a spastic element, peroneal or otherwise, cases of hollow or claw foot, rigid feet, and cases of trouble in the anterior arch so-called, can be included as suitable for this treatment as a secondary measure. I insist on no especial type of shoe, so long as they are high laced, not pointed toes, and have nothing higher than a Cuban or military heel. The more sensible the shoe the quicker the relief goes without saying.

In conclusion, I wish to emphasize that there is nothing new or original in this treatment; it is known to all orthopedic surgeons as well as the principles upon which the treatment is based. But it is all too much neglected, and in its stead there is used too much an elaborate scheme of plaster molds, upon which metal plates are fashioned, to be later modified by hammering, tempering, etc.

Let us get back to simpler methods based upon physiological principles even if our patients make us fewer visits and our pocketbooks suffer thereby.

White Flour—At last public attention is beginning to be focussed upon the shortcomings of white flour. Physicians have known for many years that the excessive grinding, bolting and bleaching processes necessary to secure the beautiful and much advertised white flour, detract very materially from the food value of the final product. However, the propaganda of manufacturers as to the beauties and fluffiness of such flour, as well as the various flour products, has been quite effective in "educating" the public to demand these products. The pendulum is now beginning to swing and the public is getting interested in knowing the facts. Manufacturers of white flour may be expected shortly to launch another "educational" campaign of the kind that creates a desire for white flour or they will be compelled to change machinery and methods and make more of a much better quality of flour.

The New York City Board of Health has recently changed their sanitary code by amendments as follows:

RESOLVED, That Article 9 of the Sanitary Code be amended by adding thereto two new sections to be numbered 141 A and 141 B, to read as follows:

Section 141 A. Bleached flour to be conspicuously marked or labeled. No flour, to which oxides of nitrogen, or nitrous acid, or nitrates, or cholorine, or any other chemical bleaching agent has been added, shall be brought into, or held, kept, sold, or offered for sale in the City of New York, unless the package or container shall be legibly and conspicously marked or labeled with the words "Bleached with....." (giving the name of the bleaching agent used). . . .

Section 141 B. Bleached flour products intended for human consumption to be conspicuously marked or labeled. No product intended for human consumption shall be brought into, or held, kept, sold, or offered for sale in the City of New York, which is made from flour to which oxides of nitrogen, or nitrous acid, or nitrates, or chlorine, or any other chemical bleaching agent, unless the product is legibly and conspicuously labeled or marked with the words "Made from flour bleached with....." (giving the name of the bleaching agent used).

16	*NO. 16. Chiropractic Anti-Health Initiative.* Creates Special State Board composed exclusively of Chiropractors, as special favor to unlicensed Chiropractors, who refuse to take State Examinations provided by present laws of California; grants members of Chiropractic Board power to license themselves, without any examination—upon payment of $25.00, and then issue licenses to reciprocal allies upon similar generous terms. Neglects to define chiropractic but practically presents licenses to unexamined persons to practice this undefined method of treating diseases; destroys value of public health statistics by permitting grammer school graduates of so-called chiropractic "colleges" to report on infectious and contagious diseases and sign death certificates. Vote "NO."	Yes	
		No	X

More Education, Not More Boards

The pernicious Chiropractic measure has been rejected by the California Legislature five times and by the sound sense of the people at two previous elections.

Osteopathic-Chiropractic-Anti-vivisection campaign literature would mislead the uninformed into believing that this is a contest between competitive schools of healing. It is a contest between education and ignorance; between creating irresponsible Boards for the special exemption of special groups or maintaining one Responsible Board to insure competent and impartial administration of the law for the protection of the public.

California has a competent Board of Examiners created by law, charged with the duty of determining by impartial examination the qualifications of all applicants, including chiropractors and osteopaths, who desire to treat diseases, injuries, deformities, physical or mental afflictions of human beings. Examinations are necessary to safeguard the lives and health of the people from incompetents, impostors and quacks. Citizens have the right to expect that anyone the State licenses shall possess a certain amount of knowledge of the causes and courses of diseases and the complex functions of the intricate human machine.

Examinations are open to all qualified applicants. Chiropractors have taken and have passed the examination and are now legally licensed and practicing in California. Any chiropractor who can meet the reasonable requirements of the present State law and pass a 75 per cent examination can receive a license.

To create a new Board for the special benefit of those who are unable or unwilling to take the State examinations is to approve ignorance and license lawlessness.

To create two Boards to do what one Board is doing effectively and economically is extravagant legislation.

Chiropractors and osteopaths constitute only two of the twenty-seven drugless cults of California. If a new Board is created for chiropractors and another new Board for osteopaths it is obvious that the other twenty-five drugless cults are equally entitled to Special Boards. This would result in a chaotic condition constantly menacing the public health.

The California Legislature at five different sessions carefully investigated and considered chiropractic demands for a new Board based upon charges that the present Board of Medical Examiners is incompetent and unfair. Each time the chiropractic charges were found untrue, and the Chiropractic bill was consequently rejected five times as without merit.

Insurance companies, industrial accident commissions, railroad companies, great industrial plants, the Army and Navy, fraternal organizations, who are intelligently interested in protecting the health of their working forces, would release educated physicians and surgeons and place chiropractors in full charge of their medical, surgical hospital service—if—chiropractors had any substantial part of the merit proclaimed in their campaign literature.

The law governing the Board of Medical Examiners has been upheld by our Courts as valid, reasonable and enforceable without one dissenting opinion. The present Board is impartial and able. If the present Board becomes incompetent or unfair the Governor has authority to select a new Board. The courts can review and reverse the Board's decisions. Such a well-selected, responsible Board assures all applicants of impartial and competent consideration and assures the people of California adequate protection.

Vote "NO" on Anti-Health Initiatives Nos. 16, 20, 28.

WHAT THE GENERAL PRACTITIONER CAN DO TO IMPROVE MATERNITY CONDITIONS IN CALIFORNIA

By R. KNIGHT SMITH, M. D.

Statistics have been compiled showing that the care given pregnant women in the United States is below that of some sixteen other nations, as shown by morbidity and mortality rates. How correct these figures are I personally cannot say, although I have the impression, and it is only an impression, that they fall short of rather than exaggerate the conditions that actually exist. However, assuming that the obstetrical care in the United States is markedly below that given in other countries, at whose door does the responsibility lie? The obstetric specialist—the general practitioner—the midwife—or the patient?

I have had a survey of the birth registrations for the year 1921 in the City and County of San Francisco made, submitting the names of all doctors who work in obstetrics and gynecology, either in whole or in part, and who otherwise do not have a general practice, and the following figures have been obtained.

Total number of birth certificates examined	9311
Signed by above-named obstetricians	1343, or 14.4%
Signed by general practitioners	7063, or 75.9%
Signed by midwives	905, or 9.7%

The Bureau of Child Hygiene, replying to a request for information regarding the situation at large in California, reports that of 1000 cases taken at random at Children's Conferences throughout the State there were 829 attended by physicians; 43 by midwives; 2 by nurses; 25 by untrained individuals and 1 unattended.

From these figures I think you will agree with me that the major responsibility with obstetrical care rests upon the general practitioner of medicine. A little less perhaps in the centers of population than in the rural districts. In California the midwife is almost a negligible question, except in the cities, and even there it does not amount to more than 10 per cent.

With this question answered in the affirmative, namely, that the need of improving maternity conditions does exist and that the general practitioner is responsible for the care of at least 75 per cent of the cases in our centers of population to 95 per cent in the rural districts, the next question is what means are being used or could be used to meet the situation? I think this question can best be answered under the following headings:

1. *Educational*—
   - (a) Primary or obligatory medical instruction;
   - (b) Secondary post-graduate or non-obligatory medical education;
   - (c) Education of the patient.

(1a) Primary medical educational facilities have progressively advanced in efficiency during the past generation. The primary educational requirements, the preliminary course of study, the limitation of the number of students, the advance in laboratory methods, the increase of clinical material with the added fifth year of interne service before graduation, have given the public better educated medical service than it ever had from corresponding classes in the past.

(1b) Secondary non-obligatory or post-graduate instruction is desired by the vast majority of general practitioners, but the opportunity for receiving such instruction is not so easily obtained as it ought to be. Much good would be accomplished if it were possible to make short, intense, special courses available for the general practitioner throughout the State, and I look to the so-called extension courses in our Universities as a partial solution of this problem.

(1c) Education of the patient: I am of the opinion that there is no part of our physiology about which there are so many old wives' tales and ignorance on the part of the public as there is about the reproductive functions. On only one phase of this subject has the public a clear idea, and that is with regard to childbed fever. They are definitely sure that a rise of temperature post-partum is an infection, and that it is always caused by the medical attendant, and he is consequently severely criticized when such an event occurs without any regard to its real cause.

During the past two decades the feminist movement has surged rapidly forward and coincident with its development there has been a corresponding increase in the spread of information regarding prenatal care of the pregnant woman, and postnatal care of the child, as evidenced by the growth of popular literature on prenatal care, official and non-official, that is being distributed mainly through the American Child Hygiene Association and the establishment of child hygiene centers by this or similar associations, partly or wholly directed by the efforts of State Health authorities.

The entire nation has been committed to a five years experiment in the so-called Shepard-Towner Act, which commits the National Government to the contribution of a sum of money to each of the States that raises a similar sum to be expended in the studying and spread of information of these two subjects. It would seem almost useless to argue that any means that will increase the knowledge of the people on this subject ought to be employed, but John Fiske, in his admirable history of "The Beginning of New England States," says in effect that there is no danger of our re-establishing a King in this country because men's minds are on guard against it, but there are many forms of autocracy which are just as dangerous to the liberties of the people as a monarchy, and we must be most careful to avoid creating an agency which would tend to undermine either directly or indirectly our form of government, and in my opinion State medicine would do it. Therefore, it behooves us as medical men to see that this movement, instituted as an educational one, shall continue to be educational and not administrative.

2. *Individual Effort*—Cragin, in pointing out the disagreeable side of obstetrical practice, says: "And yet no one should engage in this line of work and no one deserves success in it who is

not willing to respond at once to the call of the woman who has entrusted herself to his care, as it carries with it greater moral obligations on the part of the latter to be loyal to her in every way than do any other engagements in medicine," and to which I add "Amen." In other words, he who engages in obstetric work should have the spirit of service beyond that of any other part of medical life.

I believe the first consideration of this individual effort by the general practitioner should be the organization of his work so that he would be sure to give adequate service to the prospective mothers who place themselves under his direction expecting proper care. The important phase of this organization is first, the spirit to do good work on the part of the medical man—and no amount of training will do any good if the spirit of service is absent. The outward manifestation of it is evidenced by the arrangement and equipment of his place of business (his office) so that his patients will have the opportunity to consult him largely at their own convenience, getting information and direction regarding their condition and its care, the preparation necessary for surrounding the delivery of the patient in her home with sterile conditions, together with the recording of the patient's history and laboratory findings, so important as an impetus to do good work and as self-protection against liability suits.

These things are so fundamental that no matter how small the community they should be carried out because inadequate service is the parent of inadequate pay for this class of cases, and inadequate compensation is largely the reason why the medical profession as a whole looks on this, the most important phase of medical life, as a drudgery which has to be borne to retain the medical work of the family group.

I feel that more attention to medical economics should be given during the period of obligatory medical study in the attempt to keep the young medical man from groping about first one way and then the other before he finds the best methods of caring for his patients.

Having supervised the patient during her pregnancy to term and the problems of the actual delivery at hand, how is the general practitioner to best meet and answer them?

With proper medical equipment and supervision of the pregnancy, the questions are already largely solved by prevention of some complications and providing the "how" to accomplish the desired results when it is determined what to do and when to do it. Just here, by way of parenthesis, may I lay stress on one or two things which have seemed beneficial to my patients during their pregnancy: (1) the limitation of the amount of, particularly, the higher proteid foods, and such vegetables as are followed by the excretion of calcium oxalate crystals in the urine; (2) testing for the reaction of the urine with methyl red solution as suggested by Dr. Martin Fisher several years ago, followed by the use of alkalies when the reaction is acid to that reagent; and (3) the avoidance of over-exertion during pregnancy.

It has seemed to me that these suggestions have given my patients a little less discomfort than they otherwise would have had, and the incidence of toxemia in my private practice has been about one-third the average quoted in our text books.

The phenomena which we call "parturition" is an orderly sequence of occurrences taking place within a more or less elastic limit of time, and any very considerable deviation from the general average is abnormal and likely to be attended by untoward results for either mother or child, or both, whether the labor be too rapid or too slow.

It is difficult to realize that in a physiological function like labor that some kind of operative procedure is necessary to assist delivery of the child in one case out of every four, and it is in the interests of the patient, and reflexly of her medical attendant, to abstain from exposing her to the risk of infection, particularly by the use of vaginal examination and manipulation. Under no condition in a normal labor should one be made prior to the time when the presenting part has passed the pelvic brim, for the reason that if the presenting part does not pass through the pelvic brim delivery by the natural passages will not be accomplished without exposing the patient and her child to grave danger from injuries or infection, or both. In all presentations that fail to pass through the brim after the test of labor my personal preference is for the operation of Caesarian Section to that of forceps or version, giving as it does a lower risk to both mother and child, and where we have avoided infection by not making vaginal manipulation, the operation is attended by little danger.

The demand of the patient to be relieved of the pain of childbirth and our desire to ease the suffering of the patient is the foundation of much of the morbidity and mortality that the women of our country are affected by. The use of drugs, such as opium, twilight sleep, and anasthesia prolong labor and increase operative interference, which is inevitable and is followed by the increase of morbidity and mortality to both mother and child.

No more pernicious doctrine can be taught than that which converts the normal delivery into an operative one, whether incidental to the use of drugs or predetermined by the medical man to merely finish the job, for however skillful one may be they should remember that "boys flying kites haul in their white-winged birds, but you cannot do that when you are flying words," and be careful not to advocate operative means in normal cases because it is not in the interest of their patient, as any operation is followed occasionally by untoward results, and their example will be followed by unskillful men who will have more disastrous results for their patients, with consequent loss to the State in citizenship.

Sheppard - Towner Bill — When the Sheppard-Towner bill was under discussion in Congress it was opposed by the only woman member, Miss Alice Robertson, who said among other things that "it will not help the mothers of America one bit, but will give a lot of jobs for others in the bureaus at Washington."

OBSCURE REFLEX SYMPTOMS OF TEETH, TONSILS AND SINUSES, ESPECIALLY THE SINUSES.

By ROBERT B. SWEET, M. D., Long Beach.

Since the advent of the era of the study of focal infections we have learned to consider lesions of the teeth, tonsils and sinuses collectively. We have learned that they have a common bacteriology and that they can and do produce remote infections in almost any tissue or organ in the body. But there is a tendency to look for gross lesions. By the aid of transillumination and the *X*-ray we search for the darkened areas of the sinuses and the indications of apical lesions of the teeth, often failing to find the more obscure lesions which may not be revealed even by our modern mechanical methods. It is to these obscure lesions which produce marked and intense reflex pain that I wish to direct your attention. In taking up the consideration of the pains and aches produced by lesions of the teeth, tonsils and sinuses, we discover that we have to deal with the common innervations of these structures through the branches of the fifth nerve, which enables us to understand the intricate manner in which they are connected. It is not the aching, decayed tooth; the sinus discharging pus; the hypertrophied turbinates; the impinging deflected septum; or the bulging bullaethmoidalis, so easily discerned by the casual observation that gives us the greatest trouble. It is those obscure lesions which produce much pain that tax the diagnostic acumen of the modern specialist.

Of the familiar reflexes produced by the teeth we well know the facial neuralgias and the lancinating pains, often remote from the site of the offending member. The pains in the eye, the congested conjunctival vessels, the supraorbital pains and aches in and about the ear. The earache caused by an impacted third molar is not an infrequent occurrence.

In looking about for perhaps the most obscure lesion of the teeth producing the greatest amount of disturbance, I have selected the dental pulp nodules. Not being well enough informed upon this subject personally, I have abstracted an article by Norman and Johnson (New York Medical Journal, July 20, 1921), that this paper may be more comprehensive in its scope; and to bring to the attention of the eye, ear, nose and throat physicians this phase of fifth nerve disturbances that should be given consideration in our efforts to solve some of the perplexing problems incident to fifth nerve neuralgia.

Neuralgia, defined in its primary sense, means pain, or a painful sensation of a definite type, limited to the sensory distribution of a peripheral nerve, or nerves. This pain may be referred to the surface distribution of the affected nerve, pressure on the areas of which causes a typical but not severe pain, which we are pleased to term neuralgic in character. In treating the neuralgias, our therapeutic resources are directed to a temporary or permanent relief of the chief symptom, pain. The causes of trigeminal neuralgia are many, and are mentioned for purposes of review as follows: The teeth play a predominant role, perhaps undergoing a constructive or destructive pathological change, or because of a constitutional defect in shape, position or development; affections of the gums, of the jaw bones, the cranial sinuses, and the mastoid, frequently produce neuralgias of the fifth nerve and associated neuralgias that are difficult to differentiate from a regional point of view; diseases of the eye, as iritis, cyclitis, iridocyclitis; diseases of the ear; constitutional diseases, as arteriosclerosis, malaria, anemias, diabetes mellitus (this disease being particularly prone to attack the teeth and gums), syphilis; the exogenous and endogenous intoxications; non-progressive convalescent states following acute infections and surgical procedure with pyogenic complications; the metabolic diseases with their associated endocrine disturbances; tumors of the Gasserian ganglion, of the brain, of bone in the adjacent vicinity or inflammation of the bony structures within the neighborhood of the nerve. Indeed, it may at times be the initial symptom of tabes dorsalis, and Oppenheim cites a case of multiple sclerosis beginning as a facial neuralgia. It is the purpose of this article to emphasize the necessity of excluding the presence of pulp nodules in apparently normal teeth, in all cases of intractable neuralgia, before one hopelessly resigns oneself to a state of helplessness in treating these cases. Pulp nodules in apparently sound and healthy teeth, with little or no reaction to the ordinary tests, are difficult of diagnosis. Pulp nodules, present in decaying teeth, are comparatively easy to detect, and their removal is but part of the operation, extraction or devitalization deemed necessary by the operator for that particular tooth.

Pulp Nodules—Pulp nodules are small masses of calcic material suspended in the pulp substance which, by reason of their progressive formation, effects a mechanical displacement to the point of strangulation, with resultant death of that tissue. They are commonly found in the bulb portion of the pulp, but may occur in the root portion, assuming a number of forms, those in the bulbar portion being round or nodular, while those in the root portion, are fusiform or spindle-shaped. They are more frequently mutiple than single, and it is believed that the larger nodules are formed by the coalescence of the smaller ones.

Symptomatology of Pulp Nodules—There appears to be no relationship between the frequency of occurrence of pulp nodules and the production of symptoms. They do not produce symptoms with any degree of consistency. They may be present and apparently do no harm, and, conversely, their presence may initiate an irritation of the terminal dental nerve filament because of mechanical pressure. It is a reasonable assumption that these nodules should produce symptoms in every case, but the converse is true in the majority of instances, paradoxical as it seems. This discrepancy between cause and effect may be accounted for by their slow formation, permitting the dental pulp to accommodate itself to the change within its tissue, without giving rise to symptoms. However, it appears that when the nodule or nodules become large enough to strangulate or obliterate the pulp tissue, symptoms are produced. The symptoms are the result of mechanical irritation, by the nodule or nodules, to the terminal nerve filament within the pulp tissue. Usually the local symptoms are hyperesthesias, not limited to the particular tooth or teeth affected, but affecting the pulps of all the teeth on that side of the dentures. Black has noted that general pulp hyperesthesia may be the precursor of an acute gouty or neuralgic attack. Unless the nodule or nodules are located and removed, continuous pain stimuli are transmitted by that branch of the fifth nerve supplying the affected tooth or teeth. It is known that if a sensory nerve transmits continuous pain stimuli, fatigue will result. Fatigue is the end result of biological changes, in nerve tissue, necessary for the performance of specific function. If fatigue is prolonged by reason of constant irritation (pain) to a terminal dental nerve filament, neuralgia of the main nerve

trunk results, with reflex neuralgic manifestations in its branches. This explains why the neuralgia does not disappear until some time after the local agent is removed. Time is necessary for a complete recuperation of the nerve itself.

So much for the teeth. As for the tonsils I have but passing comment to make. They have been given a great deal of consideration and their part in the production of pains and aches is quite generally understood. Probably the diagnosis of toxic neuritis covers the greater part of their etiological importance.

The sinuses constitute the most important and interesting division of the subject. I will not take time to enumerate the usual local pains about the antrum, the frontal headache, caused by acute sinusitis. The right maxillary sinusitis may manifest itself by a left supraorbital pain. The occipital and vertical pains and the pounding ears of an acute sphenoidal sinusitis are generally understood. In cases of acute sinusitis it is important not to be misled by the location of the pains, but the physician should seek by every method available to locate the offending sinus, and also make sure that it is only one, because several sinuses are frequently involved at the same time.

Your attention is directed to that class or type of sinus lesions which Sluder has classified in his book on "Headaches, and Eye Disorders of Nasal Origin." The cases showing small pathological changes but severe pain. Sluder's three classifications are the syndrome of nasal ganglion neurosis, vacuum frontal headaches, and hyperplastic sphenoiditis. Before I became acquainted with the contents of his book I was struck by the peculiar symptoms I had observed in a few cases that I had not remembered as being described in my text book. At least they did not correspond to the classical descriptions commonly taught. After becoming interested along this line I searched back through my records that I might ascertain how many of my cases I could place in this category. Of about four hundred cases of sinus trouble of which I had X-ray pictures and case records I was able to select only nine that I felt corresponded to one or the other of Sluder's classes. A clean-cut diagnosis of these conditions is not an easy task and usually the diagnosis is only confirmed by the results of the treatment. Take a case of recurrent intense headache extending over a long period of time often accompanied by vertigo and nausea; with the history of going to bed for three or four days, and finally resorting to a hypodermic of morphine for the relief of pain. When upon examination one finds the septum straight, the middle turbinate normal or slightly atrophied; no impinging areas; no pus or mucous or glarry secretion from any sinus, and transillumination and X-ray negative. And then upon opening of the nasal frontal duct have all the symptoms subside and the patient be relieved from that time on, one is warranted in making a diagnosis of vacuum frontal headaches.

Many of these patients have been seen by many specialists, who in the absence of any noticeable secretion have not made the diagnosis of sinusitis. Many of these patients have suffered for ten, twenty or even forty years and have been relieved by a single operation requiring less than twenty minutes' time. The cases of nasal ganglion neurosis and hyperplastic sphenoiditis are even more obscure, and no doubt if physicians were better trained in diagnosis and had more knowledge of the pathology of diseases of these areas, many more definitions describing more minutely these pathological lesions would be available.

I do not claim that ganglion neurosis and sphenoiditis are not caused by infection, or that they are always free from secretions. The point is that the secretion is not always in evidence. I have examined some patients time and again, finding the mucous membrane perfectly dry, but later on the tell-tale muco-purulent secretion would show up. I have always felt that the action of cocaine in shrinking the membrane acted not only to promote ventilation but also to facilitate the drainage of secretions. It is a fact also that the effect of negative suction or syphonage has had a most favorable effect upon these conditions. The Nichols nasal syphon used at home has a much better effect than the suction treatment in the office. After proper treatment the relief to these patients is so striking that it compensates for all the time and energy required to bring about favorable results.

CASE REPORTS

A man of 64 years of age had had headaches for the past eighteen years. He had consulted various specialists in several large cities, all of whom had suggested the possibility of sinus trouble but none had ever discovered enough evidence to warrant any operative procedure. He had had eight different prescriptions for glasses but was not wearing any of them. The attacks were periodic, occurring about every two weeks. They would begin with a slight dullness over the left eye, accompanied by gastric distress, nausea and ended usually in vomiting. He had long since given up hope of receiving any relief aside from opiates and a rest in bed for several days. His business was necessarily seriously interfered with. At no time during these attacks did he have any discharge from the nose. He was pale, his facial expression was distraught, thoroughly discouraged but willing to have anything done that would afford any hope of relief. He had two X-ray pictures that had been previously taken which showed nothing. But not being content with that I insisted on having another. This picture showed nothing. On examination the membranes of the nose were pale and slightly atrophic. The septum was straight. The middle turbinate hung free. There was no impingement, either against the septum or ethmoidal region. The bulla ethmoidallis was not prominent. There was no secretion, not even glarry mucous present, even after severe suction. The nasal frontal duct appeared patulous. Notwithstanding this lack of anything to warrant operative procedure, I proceeded to excenterate the anterior ethmoid cells, the agger-nasi, at the first sitting. Much to my surprise no pus or mucous was discovered, and only the usual amount of bleeding. This was followed by a marked improvement in the symptoms. The patient became enthusiastic over the prospect of other results. After that, whenever he felt an attack of headache coming on, he would come in, and with a shrinking up of the parts with cocaine and a slight curretage of the cells he would get relief. I became suspicious that the effects were either psychic or due to the soothing effects of the cocaine. Consequently, I frequently omitted the

cocaine and used adrenalin instead, with almost but not quite the same effect. The recurrence of attacks became less and less frequent. About this time, however, after I had felt that I had been dealing with a dry sinus, I began to notice the presence of a thick mucous which would flow down after the treatment and with the aid of suction. The patient also would tell me that he would often expectorate mucous an hour or two after the treatment. This fact has led me to question the existence of the so-called dry sinusitis.

Woman, age 32, three years ago began with periodic headaches, which gradually increased in intensity until they became severe enough to put her to bed for a period from three or four days to a week. She had been thoroughly examined and given a variety of treatments, including milk diet and rest, endrocrines and glandular extracts. But to no avail. Her eyes had been refracted. Sinuses and teeth had been examined by the X-ray. The sinuses had been examined by several physicians and pronounced negative. The patient's headaches were accompanied by vertigo, nausea, and even periods of delirium, often requiring opiates for relief. During the interval between attacks she was perfectly well and comfortable. On examination the nasal passages were entirely free from any signs of secretion, congestion or impingement. The possibility of frontal vacuum sinusitis was considered and a frontal sinus opened, but to no avail. At a secondary sitting the ethmoids were opened. Still no results. Finally, the left middle turbinate was removed, and the sphenoidal atrium exposed to view. There was a very small opening, hardly large enough to admit of a small probe. The orafice, however, presented a puckered appearance. The sphenoid was opened and the atrium enlarged. No discharge followed. This resulted in modifying the severity of the next attack very remarkably. Since then the attacks have become much less frequent and much less severe, until it has been possible to keep them entirely under control by local treatment of cocaine to the atrium, which is prone to close even after free opening has been made with a punch. There has never been any evidence of mucous or pus.

CONCLUSIONS

In searching for the cause of reflex pains of the fifth nerve and its connections through the sphenopalatine ganglion we should consider the teeth, tonsils and sinuses collectively.

The most intense reflex disturbances are often found in patients where the smallest amount of pathological changes are present. The study of this subject suggests that there is still much to be learned about reflexes of the fifth nerve.

Fadism in Medicine — No doctor will be held guiltless who attempts to practice medicine without being familiar with, and willing to utilize, the various approved, auxiliary methods for making a diagnosis.

Likewise, no doctor will be held guiltless who allows his interest in, and enthusiasm for, one special trick to overshadow discretion and blind his perspective. As important as is the test-tube, microscope, and X-ray, a stubborn dependence on their findings alone would often be suicidal and homicidal.

Doctors are human, and it is a trait of humans everywhere to follow fads which often lead to extremes, but certainly no profession and no class of humans need, more than doctors, to sit steady in the boat and make haste slowly.—Editorial, Southern Medicine and Surgery, August, 1922.

PHLORIZIN GLYCOSURIA IN THE DIAGNOSIS OF PREGNANCY *

By MERRILL W. HOLLINGSWORTH, M. D.
(From the Johnston-Wickett Clinic, Anaheim, Calif.)

A review of the attempts to formulate some method of diagnosis of pregnancy by laboratory methods convinces that the necessity for such a test has been felt for some time. Although the menstrual history gives presumptive evidence of the existence or non-existence of pregnancy, we are all familiar with the occasional patient who menstruates several times after becoming pregnant, or even throughout the gestation period. The patient with a history of irregular menstruation before marriage presents an equally perplexing problem. And sometimes the question arises whether the diagnosis should be fibroids alone, pregnancy alone, or fibroids and pregnancy. In such cases a dependable test for pregnancy would be of inestimable value.

Bar and Ecalle, in 1919, named as reactions specific in pregnancy the complement deviation, Abderhalden's dialysis, and the intradermal reactions. To these may be added the epiphanin and cobra-venom reactions and the renal glycosuria, epinephrin glycosuria and phlorizin glycosuria tests.

The laboratory work on which this report is based is limited to the phlorizin glycosuria test, which, like the renal glycosuria and adrenalin glycosuria tests, depends on the occurrence of glycosuria during pregnancy, first noted by Blot, in 1856, later by Duncan, in 1882; the frequency of its occurrence is stated as 86 per cent by Hofbauer, 75 per cent by Payer, 5.75 per cent by Williams, 70 per cent by Stolper, 68 per cent by Berg, and 4 per cent by Cron. Klemperer, in 1896, suggested that the glycosuria of pregnancy may be due to a lowered permeability of the kidney for sugar. Hofbauer, in 1899, considered it due to functional derangement of the liver; in 1911, he undertook to prove this by tests of the liver function and histologic studies. Lenhartz, in 1908, stated that it is relatively harmless. Cristalli, noting that Schroder, Reichenstein, Falk and Hesky, and Bartels had reported a large percentage of levulosuria in pregnancy, supported Hofbauer's hypothesis, as did Sachs, Strauss, and Sebatowski. The investigations of Hynemann, Landsberg, and Heinrichsdorff, however, disproved Hofbauer's hypothesis. They showed that in cases of any derangement of the liver there is some degree of eclamptic toxemia. At this point in the history of the subject blood sugar determinations were applied to the problem. Benthin claimed that the blood sugar during pregnancy is normal or subnormal, a fact corroborated by Novak, Porges and Strisower, Frank, Jacobsen, Mann, and Bergsma. Reichenstein, and later Stolper, considered the glycosuria of pregnancy to be due to a disturbance of ovarian function. The latter undertook to prove his contention by animal experiments, in which he demonstrated that hypo-function

* Read before the Section on Obstetrics and Gynecology of the Medical Society of California, at Yosemite National Park, May 16, 1922.

of the ovaries is accompanied by a decreased glucose tolerance, and a hyper-function by an increased tolerance. Von Jaskch, Lanz, Hofbauer, and Payer showed that the glucose tolerance in pregnancy is lowered. Bergsma stated that the glycosuria of pregnancy is not dependent on any derangement of liver function, but upon a physiologic hyper-function of renal epithelium. Hirschfeld, in 1910, stated that glycosuria of pregnancy is not related to true diabetes mellitus, and Shirckauer, in 1912, pointed out the important differences between the two conditions. Caldwell and Bibbs suggested that the glycosuria of pregnancy may be due to a phlorizin-like substance circulating in the blood. Novak, Porges and Strisower, in 1913, showed that the glycosuria of pregnancy is due to an increased permeability of the kidney for sugar, glucose, lactose, and levulose, and is not accompanied by a rise in blood sugar. Their work eliminated the possibility of derangement of the liver and proved Klemperer's earlier theory.

Frank and Nothmann produced glycosuria in women two to three weeks pregnant by the ingestion of 100 gm. of pure glucose; specimens of urine were withdrawn every fifteen minutes and tested for sugar. In pregnant women sugar appeared in forty-five minutes and was slight, never more than 0.9 per cent. Blood sugar determinations were made before and during the test. The authors stated that in non-pregnant women the test is consistently negative. In thirty cases, pregnancy was demonstrated in the first three months. They concluded that it is sufficiently accurate to be applied to the diagnosis of early pregnancy. Nurnberger, in 1921, in a discussion of the results obtained by Frank and Nothmann, stated that the possibility of hepatic disease, thyroid intoxication and latent diabetes must be eliminated. He repeated the experiments of Frank and Nothmann and substantiated their findings; however, he stated that this type of glycosuria disappears after the third month. Seitz and Jess, in 1922, reported that they had produced glycosuria by the ingestion of 100 gm. of glucose in fifty women from two to eight months pregnant, with a rise in the blood sugar curve to physiologic limits. McWallis, in 1921, administered 50 gm. of glucose to pregnant women and found that the blood sugar curve in pregnancy is identical with that of hyperpituitarism. The epinephrin glycosuria test was originated in 1922 by Roubitschek. The patient ingests only 10 gm. of glucose in 200 cc. of tea, and thirty minutes later receives hypodermically 0.5 cc. of 1-1000 epinephrin solution. This test, like Frank and Nothmann's simple glycosuria test, is not absolutely diagnostic, but accredited by the author as a valuable addition to the early diagnosis of pregnancy.

Kamnitzer and Joseph, in 1921, reported their results from the use of phlorizin in the diagnosis of pregnancy. Their work is based on the production of some type of "renal diabetes" by the injection of phlorizin, a fact discovered by Von Mering, in 1886, and later studied by Lusk, Halsey, Kraus; Lusk, Reilley and Nolan; Stiles and Lusk, and many others. There seems to be some doubt whether the term "renal diabetes" should be applied to phlorizin glycosuria. It is a form of glycosuria in which there is no change in the content of blood sugar; the glycosuria results from a lowered permeability of the renal epithelium for blood sugar. This allows the sugar normally present in the blood to filter through the kidney, so that the blood sugar is actually diminished.

The procedure employed by Kamnitzer and Joseph consists of the injection of 2.5 mg. of phlorizin intramuscularly, and analysis for sugar of the urine passed thirty minutes later; 30 mgm. of phlorizin is dissolved in 30 cc. boiling distilled water and 2.5 cc. of the resulting 0.1 per cent solution is injected while still warm. This amount is one-tenth of that calculated to produce glycosuria uniformly in the normal person; so small an amount is supposed to be sufficient to produce glycosuria in the pregnant woman, since the patient already is on the borderline of renal diabetes. Kamnitzer and Joseph employed in their analysis Nylander's sugar reagent which makes use of a bismuth reduction instead of the usual copper reduction, and is very much more sensitive than the copper reagents. They reported all pregnant women to give a positive test, not stating how many were tested, 10 per cent of seventy-seven non-pregnant a positive test, and all men (ten in their series) a negative test. The positive test may be obtained two weeks after conception, they stated. Their conclusion was that a negative test excludes pregnancy.

Author's Series—The Kamnitzer and Joseph method of diagnosing pregnancy has been applied in a recent series of fifty-four cases in the Johnston-Wickett Clinic, consisting of twenty-eight non-pregnant women, nineteen pregnant women, and seven men. The decisive results of the originators have not been obtained. The apparent wide variations in the susceptibility to phlorizin, as judged by the depth of the black precipitate in the bismuth reduction, was striking. In this series some of the most positive tests were in men and non-pregnant women; 21 per cent of the non-pregnant women and 28 per cent of the men gave positive tests. Besides, negative tests were obtained in two of nineteen pregnant women, leaving positive results in 90 per cent in pregnancy. The test was repeated on one of the men with a positive reaction with only 2 cc. of the solution (2 mgm. phlorizin), and a positive test was obtained again. Three of the six positive tests in non-pregnant women were obtained by the use of only 2 cc. of the solution. The two negative tests obtained in the pregnant women were with 2.5 cc., one during the third month, the other during the fifth month of pregnancy. In carrying out the test, comparison was made of the urine before and after the injection of phlorizin by the use of control specimens from the patient, since the small amount of sugar normally present in the urine gives some reduction. The conclusion concerning the phlorizin method of diagnosing pregnancy in this series

was, therefore, that it is simple and easily applied, but greatly lacking in dependability.

DISCUSSION

John Vruwink, Los Angeles—The history of the patient and bimanual examination are still the only ways we have of diagnosing pregnancy. I am sure any one practicing obstetrics would welcome any procedure that would make definite a diagnosis of pregnancy, not only when there is a question of fibroids. Some definite method that would tell us whether or not a woman is pregnant would surely prevent a certain number of operative procedures incidental to a wrong diagnosis. Any efforts that are made to find this definite method are of great value. Whenever a procedure is first brought out, certain definite conclusions are drawn. For instance, Abderhalden's test for pregnancy when first published was rather definite in its conclusions, but since then has been shown to be unreliable. The work of Hollingsworth certainly proves that there is no definite method that permits us to conclude whether a patient is or is not pregnant.

Abderhalden's test is so far the best known method, but the very complexity of that procedure itself puts it into the hands of a few specialized workers and consequently is not available to the practitioner at large. The shortcomings of Abderhalden's test in the presence of various other conditions are well known. It is a fact that the urine of pregnant women contains one or the other type of sugar at certain periods. This occurrence has been estimated to vary from 40 to 80 per cent. Whether the increased permeability of the kidney of pregnant women to sugar will be of value in utilizing it as a diagnostic procedure is questionable. It seems to me that any deductions that can be made from the increased permeability will be relative because it is never known in a particular pregnant woman what her sugar tolerance may be. It is questionable in my mind whether the ingestion of glucose or the epinephrin glucose method will result in any definite advantage, although it will be well worth while to make further observations.

M. W. Hollingsworth, closing—The Abderhalden dialysis test has been found so unreliable that there is considerable contention as to its value, not only in the diagnosis of malignancy, but in the diagnosis of pregnancy as well. Van Slyke, Vinograd, Villchin and Loseę developed a refractormetric method for the determination of serum protease with the particular object in view of applying it to the Abderhalden reaction. This is highly accurate and eliminates to a very great degree the subjective element. They found the serum of nonpregnant women showed as much ferment activity on placental albumin as the serum from pregnant women.

However, those tests based on the tendency of women in pregnancy to develop a type of renal glycosuria offer us more hope. It is from these that we may look forward to the discovery of a dependable laboratory test for pregnancy.

(Since the reading of this paper Joseph reports using only 2 mg. phlorizin and positive tests only in first three months of pregnancy. E. Schilling and M. Goebel, using this modification, find febrile patients give positive tests. Sachs finds the test of only doubtful value (14 per cent of pregnant women giving negative tests). J. Hofbauer reports further studies on alimentary glycosuria in the diagnosis of pregnancy. Bathe, and also Hollauer, report good, but not absolute, results with Frank and Nothmann's test. K. Hellmuth reports that the phlorizin and adrenalin tests must be discarded. He obtained better results with Frank and Nothmann's test.—Author.)

A SURGICAL STUDY OF ARTERIAL DECORTICATION *

By C. LATIMER CALLANDER, M. D., San Francisco
(From the Department of Surgery of the University of California.)

In 1918 Professor Halsted interested me in what was then the comparatively recent work on peri-vascular surgery reported by René Leriche of Lyons, France. In a long series of papers, Leriche has called attention to periarterial sympathetic nerve plexuses, and he specifies that certain definite clinical results follow the excision of these structures in the treatment of different clinical syndromes.

The surgical removal of these structures, an operation called by him "Sympathectomy," was conceived, proposed and accomplished in 1889 by his teacher, Jaboulay, who performed it with curative results on the femoral artery in certain perforating ulcers of the foot, and to a less successful degree on the coeliac trunks in visceral disturbances, the nature of which has not been ascertained.

TECHNIC OF THE OPERATION

Leriche has designated his operation as an "Arterial Sympathectomy," according to the arterial level at which it is performed—axillary, brachial, iliac, femoral, etc. The main arterial trunk is exposed by an incision 10 or 12 cm. long at a point a considerable distance proximal to the portion of the extremity which is affected. For example, the brachial artery is the operative site of election for disturbances in the forearm and hand, and the common or superficial femoral arteries in the foot or leg.

The external fibrous sheath covering the artery is divided over the length of the incision, and the artery, with its inner, more intimate sheath and adventitia, is now exposed. This inner sheath, which is fused with the adventitia, is grasped with tissue forceps and is incised directly on the vessel wall. Traction is maintained on one of the lips of the sheath of filmy tissue thus isolated, and this structure, containing for the most part adventitia, is completely freed from the artery throughout the wound with a knife or fine scissors.

Certain objective reactions in the hands of Leriche and his compatriots have been said to follow, and be consequent upon this decortication. During the course of the operation the arteries are progressively reduced in size to a third or half of their normal volume. Following this constriction there occurs a peripheral vasodilation, which is evidenced by a rise in surface temperature over those parts distal to the operation. A third reaction, which he notes as constantly following the operation, is a rise in the systolic pressure over the affected extremity.

CLINICAL PICTURES OF THE DISORDERS CURED BY LERICHE

We cannot fairly compare our results with those of Leriche, since our patients do not correspond in their clinical pictures to those in whom he obtained such spectacular results. In his hands arterial decortication afforded relief in a number of clinical syndromes, most of which he considers

* Read before the Surgical Section, California Medical Society, Yosemite National Park, May 17, 1922.

have, as a common feature, a condition of disturbed vasomotor balance.

1. *Traumatic Disorders of Babinski-Froment Type*—The disorder described by these men develops after minor injury to the soft parts of the limbs and is one in which the severity of the lesion is out of proportion to the intensity of the symptoms. Clinically, the disease is described as presenting a definite syndrome which includes contractures and pareses developing almost immediately after traumatism.

2. *Causalgia of Weir Mitchell*—Another rare but well-recognized disease which has yielded to this operation is the causalgia of Weir Mitchell. This syndrome in essence is a painful form of neuritis of the median nerve, and was described by him during the Civil War, and is so named from the Greek, meaning "I burn." Its causative factor is trauma, and the predominant symptom, pain.

In considering the mechanism of causalgia it is probable that we are dealing with a clinical picture caused by trauma to the sympathetic fibers accompanying the median nerve which supply the glands, capillaries, and nerve endings of the different layers of the skin.

3. *Results of Excision of Obliterated Arterial Segments*—In limbs affected by traumatic arterial obliteration, a variety of vasomotor, motor and sensory disturbances ensue. At operation an impermeable fibrous cord or the remains of scar tissue is found in which the artery cannot be recognized. Following the removal of this obliterated arterial segment, however, Leriche has noted marked improvement, and he concludes from his results that such an obliterated cord is not an indifferent structure, but a real nerve whose functions are perverted because of injury to its perivascular nerves.

4. *Spontaneous Ulcers in Amputation Stumps*—Certain ulcers which occur in amputation stumps in areas over which there is no pressure from apparatus, and which are definitely not caused by infection, are very refractory in their treatment. The stump in this condition is cold and oedematous, and any granulations present are very friable. Following decortication of the superficial femoral artery several of these ulcers have closed promptly and their scars have remained resistant enough to bear the use of apparatus.

FUNDAMENTAL DETAILS OF THE AUTONOMIC NERVOUS SYSTEM

Since Leriche states that both the mechanism of production of these lesions and that of their cure rests upon involvement of, and operative action on, the sympathetic fibers going to the affected parts, it is fitting before continuing that we review the fundamental physiologic and anatomic bases governing the course of the structures.

For this discussion a general scheme must be borne in mind, both since the facts which have accumulated are so numerous, and that results published on trivial evidence and faulty premise serve only to obscure the issue.

The autonomic nervous system of which the sympathetic fibers are but a part, includes the motor nerves which control the activity of the unstriated and cardiac muscle tissue and all glandular structure, and its four divisions take their origin in nerve cells in separated portions of the central nervous system. Excluding the three groups of mid-brain, bulbar, and sacral autonomic fibers from the scope of this paper, our interest is centered in the sympathetic division of this great system. The cord cells of the sympathetic autonomic division lie in that portion of the spinal cord from the first thoracic to the second or third lumbar segments, inclusive.

Nerve Unit of the Sympathetic System—To appreciate properly the peripheral course of the sympathetic fibers with which we are concerned in this discussion we must be familiar with the nerve unit of the sympathetic system. In common with the other divisions of the autonomic system, this working unit consists of a central and a peripheral neuron. The central of these neurons in any given segment has its nerve cell in that cord segment, and this cell sends out from the cord a medullated axon by way of the anterior root of the corresponding spinal nerve. Outside of the cord this medullated axon, in company with many similar axons, emerges from the anterior root and ends in one of the ganglia of the sympathetic system. This axon, then, is called the "pre-ganglionic" fiber of the sympathetic unit. We have said that this axon leaves the anterior root, and it does so in company with many similar axons from similar cells in the same spinal segment. As these fibers leave the anterior root they form a nerve trunk connecting this root with the sympathetic ganglion, which trunk is called the "white communicating ramus," white since this group of pre-ganglionic fibers are medullated.

The "sympathetic ganglia," about whose nerve cells these pre-ganglionic fibers ramify, consist essentially of the nerve cells of the peripheral sympathetic neurons. The peripheral non-medullated axons of these cells are known as "post-ganglionic fibers." These axons likewise are grouped into a trunk of fibers which connect the lateral sympathetic ganglia with the spinal nerve roots, and this trunk is the "grey communicating ramus," grey since it contains for the most part non-medullated post-ganglionic fibers. The characteristic common to all of the lateral sympathetic ganglia is that the nerve cells there contained send their post-ganglionic fibers, at once or eventually, back to the cerebro-spinal nerves, thence to be distributed to the body wall and the extremities.

Course of the Sympathetic Fibers to the Skin of the Extremities—When the post-ganglionic fibers destined for the skin re-enter the spinal nerves they are distributed to the periphery in the cutaneous branches of these nerves and not along the main arteries of the part, a fact of dominant interest in this discussion. While it has been generally believed that some sympathetic fibers make their way to the periphery along the sheaths of the arteries, definite proof that they follow this course has not been adduced. There is, however, this point to be borne in mind, that the sympathetic system does send fibers direct to the aorta, and that these fibers appear to spread some distance along the larger arteries. It is not unlikely that these nerve fibers cause some contraction in

the walls of these vessels, and that in this way a modification of the blood supply to the skin and muscles may take place without any direct action on the walls of the peripheral vessels.

Bearing in mind that this operation in Leriche's hands has brought about vascular dilation distal to the operative site, we have selected patients in whom we thought this peripheral vasodilation, bringing an increased blood supply to the part, might bring relief. In this series we have performed ten arterial decortications on six patients, on one of whom three arteries were stripped for disease of three extremities, and on another two arteries were stripped for trouble in two extremities.

We have preferred to make no clean-cut diagnoses in these patients, but have chosen to place them into three groups. In the first group we shall consider those in whom the arterial changes before operation were thought to be spasmodically contractile in their nature rather than permanently obliterative. In the second group will be mentioned those in whom an obliterative arteritis had seemed to play the predominant role. The third group is that of unaccounted-for pain, in which we have but one case.

CASE REPORTS

Group I

Case 1—(E. H.), male, age 38. For twenty years patient has suffered from vascular disturbances, which brought him to the hospital with severe gangrene of an amputation stump below the left knee, gangrene in various stages of progress in the left hand, and changes threatening gangrene in the Chopart amputation stump of the right foot. Amputation of the left leg in the upper third of the thigh was immediately necessary as an emergency measure.

Operations and Result: (First Operation)—A decortication of the left brachial artery was performed in the hope that the gangrene in the left hand would be arrested. Present reports (six months later) show that the patient is having no further gangrene in this hand, but that the subjective symptoms have not improved. (Second Operation)—Decortication of the right common femoral artery and a portion of the superficial femoral artery (Dr. S. Hyman) resulted in no improvement in the condition of the right foot.

Case 2—(P. O.), male, age 47. For four years the patient has had pain and vasomotor disturbances of the most severe character in both feet and lower legs, together with pain and excessive hot and cold sensations in the left hand and forearm. Soon after the onset of the pain and violent skin discoloration, a deep ulceration developed over the mesial surface of each great toe. These two ulcerations, together with the other objective and subjective reactions, have been proof to all manner of therapy over this period of time.

Operations and Result: Decortication of both superficial femoral arteries and the left brachial artery have had no effect on the painful symptoms. The ulcerated areas, however, have both healed into resistant scars and have remained healed over a two months' period.

Case 3—(E. D.), female, age 63. For twenty-three years the patient has suffered from vascular changes in her extremities until the time of her admission into the hospital, when she presented serious gangrenous lesions of the fingers of both hands, the condition of the left hand being the worse.

Operation and Result: The left brachial artery was decorticated and the operation was followed by a diminution in the pain and hyperaemia of the hand, which lasted over several weeks. At the expiration of this time the condition became as before and three fingers of the left hand were amputated because of ascending gangrene.

Group II

Case 4—(C. E.), male, age 63. The patient has suffered for several months with pain in the calves of both legs and pains in the feet. Pulsation could not be obtained in the posterior tibial or the dorsalis pedis arteries of either foot, while on the dorsal surface of the terminal phalanx of the middle toe of the left foot was an ulcerated area which extended to the bone. This ulceration was spreading and becoming gangrenous.

Operation and Result: Decortication of the left superficial femoral artery (Dr. A. R. Kilgore) was followed in several weeks by a complete healing of the ulcerated area and a disappearance of the pain. At present, more than a year later, there is a resistant scar over the area and the patient is doing hard work without handicap.

Case 5—(N. F.), male, age 67. During past two years the patient has suffered with a progressive obliteration of the arteries of the lower extremities, until at time of examination no pulsation could be demonstrated below the internal iliac arteries.. An excruciating pain in the left leg and foot, which extends into the groin, was present almost constantly.

Operation and Result: Decortication of the superficial femoral artery resulted in no improvement in the symptoms or the objective reactions.

Group III

Case 6—(C. C. K.), male, age 28. A young mechanic gouged out a portion of the mesial aspect of the terminal phalanx of the right thumb. Following healing a lancinating pain developed in this thumb and the index finger, and removal of the scar together with alcohol injection of the nerve to the thumb were of no avail.

Operation and Result: Decortication of the right brachial artery was followed on the following day by disappearance of the pain. Several weeks later, however, a second pain occurred in the volar area of the flexor muscles of the forearm, and this pain, which persisted over months, has now disappeared.

We wish to state here that we have operated upon no patients who correspond in their diagnoses or clinical pictures to those treated so successfully by Dr. Leriche, and it would be obviously illogical to pass too hasty judgment on this operation on the basis of the results of cases in our hands. There are, however, certain fundamental principles wherein we differ with Leriche. The point of primary importance is to gain the proper conception of the path of the vasomotor fibers to the extremities. After careful study of Leriche's work, one reaches the conclusion that he considers the majority, if not all, of the vasomotor fibers to the extremities follow the sheaths and lie in the adventitia of the larger arteries. We find, however, that anatomists and physiologists concur in the belief that they accompany, and are embodied in, the spinal nerves which run to these parts. If such be the case, the sympathetic vasomotor fibers must leave these spinal nerves at different levels in their course and supply innervation to the arteries from point to point as this innervation is required, and not hold to a continuous course along the arteries. It is a gratuitous assumption, then, that the continuity

of these fibers may be severed, irritated, or otherwise interfered with by a removal of a thin sheet of tissue from the body of an artery. So far as physiologists have been able to prove, the only sympathetic fibers which accompany the large arteries to their termination are those which run from the pre-vertebral ganglia to the thoracic and abdominal viscera.

There arises, too, the natural question as to whether sympathetic fibers of more than minor importance are removed at the time of operation. Difficult points in the staining of nerve fibers of the tissue removed at operation necessitate further work on this subject. It is rather striking, also, that in our cases, save in one instance, we were unable to demonstrate any post-operative rise in blood pressure or increase in surface temperature.

At this writing, then, we are forced to the conclusion that an insufficient number of observations of this operation have as yet been made, and that it is only by careful physiologic estimations of capillary, surface temperature, and blood pressure changes that a proper conclusion can be reached. In terminating this paper, however, we cannot overlook the fact that marked improvement and possible cure in several otherwise hopeless conditions have resulted from this procedure, even though the mechanism of the production of the diseases, as well as that of their cure, is as yet unexplained.

(240 Stockton Street)

Hospital Work of the A. M. A.—At the meeting of the American Medical Association in 1920 the House of Delegates placed all the Association's work with hospitals in charge of the Council on Medical Education and Hospitals.

For the tremendous work that needs to be done for the improvement of hospital service, no organization occupies a position more advantageous than the American Medical Association with its various State organizations. The work of the Association with hospitals must take all institutions into consideration, and the Council is planning to establish a list, not only of those approved for intern training, but also of those approved as non-intern hospitals. The standard applied to intern hospitals is being modified so as to apply to both groups. It is becoming increasingly important that every community be provided with adequate medical and hospital service. So much depends on the future development of hospitals, therefore, that the members of each State committee should be selected with special care. It is urged that a permanent committee be established in every State consisting, preferably, of three members serving for a term of three years, the first committee being so appointed that the term of one member will expire each year. . . .

We wish to mention especially the splendid cooperation received from the State hospital committees, which respond fully and promptly whenever requests for information or inspection are made. In a few States, notably California, Washington, Missouri, and Ohio, and to a greater or less extent in other States, the committees have been particularly active, and even aggressive, visiting hospitals and assisting in problems of staff organization or community relationships when requested by the hospital. In fact, the State committee organization throughout the country is now capable of being called into action to perform any important work, and with a thoroughness hardly to be expected of voluntary committees.—Report of the Council on Medical Education and Hospitals of the A. M. A.

IRON CITRATE REACTIONS

By F. F. GUNDRUM, M. D., Sacramento

Some years ago, Gay and others described the intravenous injection of dead typhoid bacilli into patients suffering from typhoid fever and showed that in a certain percentage of cases the course of the disease was greatly modified following the sharp reaction, chill, fever, sweat and leucocytosis which followed this procedure. Later it appeared that this reaction was in no wise specific and the same course of events could be produced by intravenous use of many foreign proteids. Latterly the parenteral injection of various foreign proteids has been used therapeutically in many conditions with notable benefit in chronic arthritides and some chronic skin lesions.

The following case is of interest because: first, the reaction was produced by a non-proteid substance; and, second, the subsequent course of the disease was modified.

CASE REPORT

Mrs. O. aged 30, admitted to the White Hospital at the end of the first week of typhoid: W. B. C. 4,000; Widal positive. This patient, only recently from Japan, evinced a great distaste for the usual typhoid dietary, especially sweets and milk. The only food she would take was rice gruel, upon which she became, as the disease progressed, exceedingly emaciated and anaemic. On this account, iron citrate, grs. ¾, was ordered to be given hypodermatically. The first dose, on the forty-eighth day of the disease, was followed by a chill, elevation of temperature to 102, pulse corresponding. On this day we were unable to explain the chill; physical examination gave no clue to its cause. Upon the two following days the nurse forgot to give the iron citrate. Upon the fifty-first and fifty-second days the same dose given hypodermatically was followed by a chill, rise of temperature to 104 and 105, with rapid defervescence. The iron citrate was discontinued. The temperature curve, which previously to these reactions had shown an afternoon elevation to between 100 and 101, remained at 99 or below until the patient left the hospital cured.

The iron citrate preparation used was of a well-known standard make, perfectly clear, and the remaining ampoules in the same box were used upon another patient without producing any reactions. Though it is impossible to say that there was no proteid in the ampoules used, its presence is in the highest degree unlikely.

(Capital National Bank Building)

Psychology—"The word 'psychology' is shamefully overworked and misused. For several years it has been the prey of charlatans, four-flushers, bluffers and ignoramuses until at sight or sound of it we are more likely to be disgusted than interested. There seems to be no end of magazine articles, books, lectures, and advertisements on the psychology of religion, psychology of advertising, psychology of adolescence, psychology of dreams, psychology of the strike, psychology of salesmanship, psychology of health, psychology of childhood, and the hundreds of other similar vague titles that force themselves upon us. The climax certainly has been reached, however, in the now prevalent question, 'What is the psychology of this situation?' or, 'The psychology of this act?' or, 'The psychology of that man?' these questions being offered merely for the sake of conversation, just as we will talk about the weather."—(Journal of Iowa State Medical Society, August, 1922.)

THE PHYSICAL BASIS OF DEEP ROENTGEN THERAPY*

By FRANK RIEBER, San Francisco.

In handling the subject of deep roentgen ray therapy from the physical standpoint, only one biological factor really needs consideration. The balance of the subject may be treated strictly as a problem in engineering and physics. Therefore, in this paper I wish first to state my biological basis and, second, to give as simple a physical explanation as possible of the laws governing the generation, transmission and absorption of roentgen rays intended to accomplish certain predetermined results biologically.

Generally stated, the biological factors are: (1) Any living tissue, if exposed to a small quantity of Roentgen radiation, is stimulated to a condition of greater activity. (2) If the amount of roentgen rays delivered to this tissue is increased, the activity of the tissue is not stimulated further, but on the contrary is inhibited or restrained. If the amount of radiation is further increased, this inhibition will eventually reach the point of actual tissue destruction. All types of tissue do not respond at the same rate to the same dosage of X-rays. In this fact lies the basis of roentgen therapy—namely, to apply a dosage to a certain selected portion of the human body which will accomplish a certain result, and yet *not* to cause damage to other portions of the body which it is not desired to affect. For example, if we wish to treat a tumor or malignant growth some distance below the surface of the body, we may direct a beam of X-rays toward this tumor, and a certain fraction of the energy in this beam will actually be delivered to the tumor and absorbed in it, and an effect in the tumor will be produced thereby. However, any beam of X-rays directed at the body acts to some extent on all tissues that it strikes. Further, the effect of this beam is strongest on the first tissue it encounters, and becomes progressively weaker as it proceeds through the body. Under these circumstances, the skin in the typical patient we are considering will absorb a greater proportionate quantity of the beam of rays than will the layers of tissue beneath the skin, and a much greater proportion of this beam than will be absorbed by the tumor. We are therefore confronted with the first limitation to our treatment. *We must limit the total energy* in the beam so that the skin of the patient does not have delivered to it and absorbed in it more than a certain total quantity of energy which we will designate as the "safe skin dosage."

The second consideration in our problem is that we wish to *deliver the maximum possible quantity* of the total radiation in our beam at the point where we desire to produce an effect with this radiation—that is to say, at the tumor itself. Combining these two conditions, we can state our complete problem—we wish to *deliver the largest permissible quantity* of roentgen rays into *a tumor without exceeding the safe limit* of radiation in any other part of the body.

Now, let us consider the X-ray, to see how its laws of generation, transmission and absorption fit it as a tool for the purpose we wish it to accomplish. First, the much discussed matter of the voltage or "spark gap" at which an X-ray tube can be excited, with relation to the effect we can produce with the X-rays. Any X-ray tube in action sends out a large and varied assortment of X-rays—all of them having different qualities. Some of these rays are able to penetrate rather deeply in the tissue before they are completely absorbed. Others are more readily absorbed and will produce no appreciable effect at a very slight depth below the surface of tissue. The best that we can do, therefore, is to state that at any given voltage or "spark gap" applied to the X-ray tube, we will generate X-rays whose *average ability* to penetrate tissue bears a *definite relation* to the voltage, or "spark gap" at which they were produced. This average penetrative ability increases with an increase in voltage.

To employ the rays from an X-ray tube for deep therapy, we find it expedient to use only those rays from the total assortment generated by the tube which have a relatively high penetrative ability, and to discard the rays which have a low penetrative ability. We are thus able to increase the proportion of rays of the total beam which will arrive at a given depth in the tissue. We accomplish this selection of rays by what we call filters—layers of metal or other substances through which the X-rays are passed on their way from the tube to the patient. These filters absorb the rays of low penetration very readily, so that very few of them get through. The rays of high penetrative ability, on the other hand, pass much more readily through the filters, and a fairly large proportion of them get clear through, and are available for purposes of treatment. The exact selection of the amount of filter required for a given voltage or "spark gap" on the tube, with a given result to be accomplished within the body, is a matter which need not be presented here in detail. Data are available from which the thickness and materials of these filters can be determined with fair accuracy if the conditions under which they are to be used are known beforehand. The general effect of filtration is to produce a more homogenous bundle of rays—that is to say, there is a smaller proportionate difference between the *most penetrative* and the *least penetrative* rays in a filtered beam. There is a limit to the amount of filtration which can be applied to any given beam of X-rays for a certain purpose. This will be readily seen when it is remembered that a filter not only stops a high proportion of the rays of low penetration for which we have no use, but that it also stops a certain proportion of the rays of high penetration which we need. Therefore, if we increase the filtration to a great extent, we will not improve greatly the quality of the rays we are obtaining, but we *will* weaken the beam, and we will therefore require much longer time of treatment to accomplish the same

* Read before the Section on Radiology of the California Medical Association at Yosemite National Park, May 17, 1922.

results—a great inconvenience and waste of time both to the patient and operator.

Let us now consider the problem of treatment with relation to the position of tissue on which it is desired to produce an effect. If this tissue is on the skin, or near the surface, we do not need very penetrative rays to reach it. Further than this, a highly penetrative ray would possess a disadvantage, in that it would not only produce an effect in the tissue we were trying to reach, but a large proportion of the ray might pass completely through the tissue under treatment, and produce effects on tissues lying deeper which we did not want to touch. Therefore, for treatment at or near the surface, a low average penetrating characteristic is all that is required. Rays of low average penetration may be produced by using a lower voltage, or "spark gap," applied to the X-ray tube. For example, most skin work and much superficial gland work may be done at a potential not exceeding one hundred kilovolts crest, corresponding approximately to a seven-inch spark gap between points.

If, on the other hand, we wish to affect tissue at a much greater depth, we should resort to the highest voltage which an X-ray tube will sustain without destruction of the tube. The penetrating rays produced at this high voltage enable us, without exceeding the safe skin limit, to get a much larger proportion of the energy delivered at a depth. But rays of this penetration can not be trained to dash into the body to a certain depth, and then stop short. If we find it necessary to use penetrative rays, we must accept the fact that these rays will not stop entirely when they have reached the desired depth, but that a considerable proportion will pass beyond that depth and in fact clear through the body. As a typical example, suppose we are attempting to treat a tumor with its center at a depth of six inches from the surface of the body, and that the body at the point where it is being traversed by the beam of X-rays has a total thickness of one foot. Suppose further that we are confining the beam of X-rays we are using to a very small cross-sectional area—in fact, suppose we are using a mere pencil of rays. Let us assume further that we are able to measure the intensity of the beam of rays at all points in its path (as we are actually able to do if we substitute for the human body an experimental tank of water or water phantom, since water has almost the same identical co-efficient for absorption of X-rays as has living tissue). If we are exciting our X-ray tube at 150,000 volts crest—roughly, a nine-inch spark gap—and if we are filtering this beam of rays to the maximum practical extent, we may find a series of measurements somewhat as follows: At the surface of the body, we intend to deliver a certain total radiation which is limited by the amount the skin will stand. Let us refer to this intensity at the skin, therefore, as one hundred per cent. If we now measure the successive intensities in the beam as we go below the skin, we will find that they fall off fairly rapidly, until when we arrive at a depth of six inches (namely, at the center of our tumor) we may find that the intensity has fallen off to five per cent of what it was at the surface. Following the beam on through, we will find progressively decreasing intensities until when we arrive at the opposite side of the body the total intensity may be down to as low as one per cent of the intensity at the skin port of entry.

Thus we see that in this hypothetical case where we are using a nine-inch "spark gap" the skin receives one hundred units (all that it will stand) and the tumor receives only five units of dosage, which is much less than the amount we should use to produce an effect of inhibition or destruction. In a case of this sort we may even deliver so slight a dosage to the tumor that we stimulate its growth, an altogether undesirable thing. Let us now see what happens if we increase the applied voltage to a very high value—say 240,000 volts—and again select a filter which will permit us to use a large proportion of the most penetrative rays, at the same time discarding those of less penetration. Assume that we pass a very narrow pencil of such rays through the same patient. If the dose be graded so that we deliver one hundred units of radiation at the surface—this being, remember, the full amount which the skin will safely stand—we find that instead of delivering five units at the tumor as before, we can now deliver possibly fifty or sixty units, and that ten or fifteen of these units will be carried clear through the body and delivered to the skin on the opposite side from the port of entry. This, in brief, is the advantage of the new intensive deep therapy. For the same equivalent safe dosage to the skin, we are able to deliver a much higher proportion of radiation at a depth below the skin. However, the radiation received by the tumor is not determined alone by the skin radiation, the depth, and the penetrative power of the ray. Another factor enters which complicates the problem very considerably, and renders it necessary for us to conduct a number of rather involved experiments in order to determine the exact ratio of the depth dose to the skin dose. This other factor we term "scattering" and it can best be expressed thus. The pencil of rays which comes from the tube may be considered as passing directly through the patient in a straight line, losing energy all of the time by reason of its absorption by the tissues. This absorption is of two kinds. The first kind results in an actual conversion of some of the X-ray energy into energy of chemical reaction or its equivalent. This is the type of absorption that produces biological effects on the tissue. The second type which we can also call absorption in the general sense of the word, consists in a loss of energy by the X-ray beam, but this energy, instead of being converted into chemical effects, is merely absorbed from the primary straight line beam of X-rays and re-radiated from the point where it is absorbed in the form of X-ray energy again.

Thus we have a primary beam of X-rays passed straight through the body, part of this beam being absorbed on the way and converted into chemical energy with resultant biological effect and another part of the beam being likewise absorbed as it passes through, but *reconverted* to X-rays which

scatter in every direction. These scattering rays are of two kinds. The most pronounced type, and only one which produces any effects which we must necessarily take into account in computing dosage, has the same penetrative ability as the primary beam of X-rays which caused it. The second type of re-radiated energy is of very low penetration, and stops before it has passed through any measurable amount of tissue. This scattering effect of X-rays was formerly not taken into account in computing dosage, because at the low voltages then in use, the penetrative ability of X-rays was fairly low, and they were therefore absorbed very rapidly. The scattering rays would thus be absorbed before they had come very far from the point where they scattered from the main beam, and would not be noticed in the total result. However, with rays of tremendously high penetration which we are now able to generate at 200,000 volts and over, the scattered energy travels very readily to a considerable distance from the point where it was deflected from the main beam. It may even be re-deflected a number of times on its divergent path. Thus we must consider in computing the radiation which falls upon the tumor at a depth below the surface, not only the primary bundle of rays which has been directed at the tumor, but all of the scattered radiation from other parts of the body which likewise happens to fall upon the tumor. To appreciate the practical importance of this, assume that we have a tumor about the size of a walnut at the depth of several inches below the surface of the body. Assume further that we are able to locate this tumor with extreme accuracy and to direct a beam of high penetrative X-rays upon it in such manner that the beam will be no larger than necessary to strike all parts of the tumor. We will now have a dosage delivered at the tumor due to the direct beam of rays, and a slight additional dosage due to such scattering rays, set up in the path of the direct rays, as happens also to strike the tumor. Now let us enlarge our beam of rays which has been directed at the tumor until it covers a very much greater area, and let us keep the radiation of exactly the same quality as before, so that in a given time we have passed as much energy into the body as the skin will permit without reaching the destructive limit. The tumor will have received the *same amount* of dosage from *direct radiation* as it formerly did. But it will have received in addition a *very much* larger amount of scattered radiation, because we have greatly increased the area of the primary beam and have therefore greatly increased the total volume of tissue which has been excited into radiating scattered rays.

The computation of the total dosage from a theoretical consideration, while it is doubtless possible, is of too great difficulty to be of practical value.

Experimental work has therefore been done on the following points:

1. To find an experimental medium which would offer the same resistance to the passage of X-rays and generate the same proportion of scattering rays as human tissue does.

This has been satisfactorily answered by the use of water. Water phantoms or containers approximating the shape of the portion of the human body it is desired to treat have been made to use in experiments.

2. The development of an instrument which when placed in a water phantom (or within the human body) and exposed to X-rays, will give readings proportionate to the strength of the biological action at that point.

This problem has been fairly well solved by the use of small cells termed ionization chambers. These cells are constructed of horn or celluloid, and lined with a layer of graphite to serve as an electrical conductor. Since the materials used in their construction correspond fairly well with tissue and with water in the rate at which they absorb energy, they exert no great disturbing influence on the measurement. A highly insulated electrical wire is led into the center of one of these small cells, and a known amount of electrical charge is placed on the wire. If no X-rays strike on the cell, normally the air within the cell acts as an insulator and the electric charge placed on the wire will remain for a very considerable period of time without leaking off. When it does so leak most of it is carried from the wire through the insulation covering it, and practically none of it passes across the air space within the cell. By timing the rate at which a known charge leaks off through the insulation of the wire, this loss can be corrected for. If, now, a given charge is placed on the wire, and the cell exposed to X-rays, the air within the cell is ionized—that is to say, the air absorbs X-rays and converts them into energy of ionization, so that the air becomes a conductor of electricity in proportion to the quantity of X-rays striking it. Due to the electrical conductivity of the wire, the charge now leaks off very rapidly. The time during which it leaks off may be measured, and after subtracting the known leakage rate of the insulation on the wire, the remaining time serves as an indication of the strength of X-rays to which the chamber was exposed. The shorter the time the more intense the radiation. In fact, the strength of radiation and the time of discharge for a known charge bear an exact inverse proportional relation within the limit of experimental error.

3. Having now obtained an experimental medium similar to tissue, and a measuring instrument capable of measuring the intensity of radiation at any point within that medium, we may proceed with our experiment. A beam of filtered X-rays produced at a known voltage or "spark gap" and filtered through carefully measured filters in order to remove the low penetrating components, is allowed to pass through such a water phantom in which, while the ray is constant in quantity, the ionization chamber is moved from point to point, and the distance at each point is measured.

By taking a very large quantity of such measurements it is possible to plot lines of equal dosage through the cross-section of the water phantom.

A chart so constructed shows the cross-section of the phantom through the mid-section of the ray, and assumes a radiation at the face of the

water phantom where the beam enters of 100 per cent. Using this value as a standard, a line is then located on the chart corresponding to the distance from the port of entry at which the radiation has fallen off to 90 per cent. This line curves somewhat and extends beyond the area of the original beam, due to scattering. Similar lines are constructed for 80 per cent, 70 per cent and so on until the entire area in question has been plotted.

A large number of such charts have already been constructed for water phantoms. Using such a chart selected for its conformity to the portion of the anatomy under treatment, it is possible to predict the intensity of radiation which will be delivered at any desired point when the full safe dose has been given at the skin.

It is even possible to use such charts in combination, so that several ports of entry may be used, and the total cumulative effect of dosage at an interior point may be predicted. It must not be forgotten, however, that when using several ports of entry, the full skin dosage must *never* be given through any one port, as scattering rays will be excited when radiation is passed in through the other ports, and some of these scattered rays will reach the skin at the first port of entry and add to the original dosage that has been given there.

In closing, a few words should be said about the present limits of voltage and the future possibilities that may increase this voltage.

The construction of X-ray apparatus to deliver extremely high voltage now presents very few difficulties, if carried out by those familiar with the work. The construction of the tubes to withstand these high voltages has not at the present time been carried beyond certain limits. The new high voltage Coolidge tube reaches its safe limit of operation in the neighborhood of 200,000 to 220,000 volts. If a higher voltage than this is used, destructive sparking, particularly around the anode end of the tube will occur. This sparking is due to an accumulation of negative electrical charge on the inside of the bulb, which then attracts sparks from the positive terminals of the tube which reach out over the glass in an attempt to neutralize this charge. If these sparks are permitted to occur too frequently they will perforate the glass. In suppressing high frequency surges in the high voltage line, the writer has been able to operate these tubes successfully for rather extended periods at 275,000 volts. Rather more watchfulness is needed, however, at this voltage, even with all of the electrical precautions that can be adopted to insure smooth operation. Without using other methods than those that have been tried, it does not seem feasible to operate the present day Coolidge tubes successfully at higher than 250,000 volts, even with this new system.

CONCLUSIONS

A tremendous advantage lies with the use of high voltage heavily filtered rays in that more energy can be delivered at a depth without damaging the skin.

It is impossible to predict the dosage at a depth without taking into account the cross-section of the in-going beam of X-rays.

Extended experimental work has enabled the construction of charts from which the exact dosage at any given point may be determined if the applied voltage, the filtration and the size of the port of entry are known.

Underweight a Delusion—Is there but one normal, healthy standard weight corresponding to every height, so that he who exceeds it is "overweight," and he who falls below it "underweight?" That this idea is a dangerous fallacy is contended by Charles K. Taylor of the Carteret Academy of South Orange, N. J., writing in The Outlook (New York) on "The Great Underweight Delusion." According to Mr. Taylor, a "stocky" boy, or a slender one, may be just as normal and healthy as one who has the "standard" proportions of the Apollo Belvedere. They are of different types, that is all. Some people are doubtless too fat and others too thin, but that fact is to be ascertained, not solely by comparing weight with the height, but by a system of measurements taking both these figures into account. Mr. Taylor has worked for years to construct a system of tables for this purpose, and thinks he has now a satisfactory method of applying his ideas in practice. He writes:

"Children are frequently slender because it happens to be a hereditary type just as it is hereditary for some to be stockier and heavier than the average. Some races are typically slender, with weight below the general average of humans.

"The very essence of our delusion is the claim that there is only one normal and healthy type of build—the 'average'—and if children (not to mention adults) happen to be more slender than this highly worshipful average, then, obviously, something is wrong with them. They are 'underweight.' A frightful term that sends whole communities into providing fattening diets for perfectly healthy children and doing everything that uncanny genius will suggest to make a lot of normal children morbid over matters they do not need to worry about.

"It might be interesting for some one to analyze the Worship of the Average. I don't know what we would do without it. Why, our whole educational system is based upon it. The average child! And that is why the duller-than-average child is perhaps prodded up a little; children brighter than the average are caught fast in the machine, so that educationally they are rarely able to come anywhere near their capacities.

"So when we insist that children should at least came up to an average in weight we are doing only what we also do in the classroom, with this difference, however: When a child's weight is overaverage, then we are likely to smile with approval; but when a child is mentally overaverage, well, we just let that child remain in the grip of the machine that keeps achievement down to the average scale of things.

"Our stand is simply this: That it is just as normal and healthy for some children to be more slender than the average and for others to be stocky or thickset, as for still others to approximate the average, that it is a matter of inherited type of build, and all we need to do is to see that a child is properly developed for his or her normal type of build.

"When a child is in good physical condition, and particularly when that child's muscles are not flabby, but firm and efficient, then we may be sure that the child's weight is correct, no matter what it is. And our work, then, is merely to see that a child has a physical development corresponding to his or her type of build.

"It will take a very serious mental upheaval to bring many of us to see that the question is health and development, and not one of weight, but we are coming to it little by little. And once this is accepted, then another question will come promptly into being. Here is this one: 'How are you going to know when a child is well developed?' Nor is this going to be difficult to answer."—(Editorial, Journal of Indiana State Medical Association.)

Detailing Physicians—Through familiarity on the part of the doctor with the U. S. Pharmacopeia, the National Formulary and New and Non-official Remedies would make "detailing" a less popular indoor sport for the manufacturer.—San Diego Medical Society Bulletin.

OVER FIFTY YEARS IN MEDICINE *

By ROBERT F. ROONEY, M. D., Auburn, California

Fifty-six years ago, or in June, 1866, I entered upon the study of medicine in the office of two medical partners in a small but central town in the then Province of Lower Canada, now the Province of Quebec. The partners kept their own medicines and there I imbibed my anatomy and physiology in the intervals afforded between the compounding of mixtures, the rolling of pills, and the mixing and folding of powders. There I was present at the setting of fractures, and the operations of minor surgery. Yes! and even the extraction of teeth—the nearest dentist being twenty miles away.

I believe such training to be good for a young man, and makes him better able to handle his own patients in his early years, rather than the student who enters college without such experience, and who begins private practice without other than hospital work, which is so entirely unlike the handling of private patients. Shortly after entering the office of my preceptors, one of them took me to visit a hopeless case of—peritonitis? The patient was a young Scotchman who had just arrived at the local hotel with his wife whom he had married before leaving the old country, and who knew no word excepting Gaelic. He came with a few pounds in cash, intending to buy a farm and become a settler. He was almost at once stricken with what was, no doubt, an attack of appendicitis, in the face of which the profession then stood helpless, calling it "peritonitis" and keeping the unfortunate under the influence of opium until death closed the tragedy.

The scene at the bedside has haunted me througout the years. The man lay gasping out the last of his life, and his young wife knelt by the bedside with her arms outflung across his body, and her face buried therein, crying out in the rhythmical cadence the Gaelic words, "Hamish sorg ma Dheelish! Hamish sorg ma Dheelish!" It was the despairing cry of a broken heart in a new world, without friends, and even without knowledge of the language spoken around her.

Often, later in life, when the abdominal cavity had ceased to be sacro-sanct, those mournful sounds came back to me, as a reminder that this poor fellow's young life might have been saved by a comparatively trifling operation.

Another instance. My preceptors were both progressive men, and their journals recording cases of ovarian tumors being cured by the injection of Tr. Iodine after tapping, they set a day for operating on a case in their practice. I accompanied them to give chloroform, if needed. The patient was past middle age with an immense tumor. She was successfully tapped and the iodine injected through the trocar into the emptied sac, but the woman lived only for a short time, and in great pain. I can yet see my eldest preceptor, sitting grief-stricken over the result.

In the autumn, I entered the medical department of McGill University. It was the year that a four-year course was first adopted and a strict examination held in Greek and Latin (at the student's choice), mathematics, French or English (at choice), dictation, to show writing and spelling and familiarity with the language. Only two other colleges on the continent, at that time, demanded a four-year course—Harvard and the University of Pennsylvania—all the others demanding only a two or three years' study. Of course, a good university course precluded the necessity of passing such examinations. I graduated and received my M. D., C. M., on March 31, 1870—over fifty-two years ago—and began practice in a neighboring town to my preceptors, where I remained until 1877, when the glamor of California overwhelmed me and I came west.

The years of my medical life have been epochal. They compass the great majority of the wonderful discoveries of medicine and surgery. This I aver without fear of contradiction. Also it has been prolific in fads and cults. At the outset of my career, Virchow had just promulgated his cell theory which revolutionized medicine; and Lister had revolutionized surgery with his antiseptic teachings and practice, and the operating rooms throughout civilization echoed to the hissing of carbolized spray, and operator, patient, assistants and observers were indiscriminately showered with the odorous vapor. My student days in the operating room are recalled by all phenol odors, which are, one and all, obnoxious to me for that reason.

But to this man we must yield all honor because to his worked out theory of wound infection is due an entire revolution in the treatment of wounds, and in surgical technique. Where thousands formerly died, thousands now recover, due to the labors of this one man.

In my graduation year died Dr. James Y. Simpson, with whose name chloroform is carved on the pillars of medical progress, and to the introduction of this agent into obstetrics, relief to woman's pangs is due. It is a curious bit of history that for this alleviation of the pains of childbirth, Simpson was bitterly assailed by the Scottish clergy, as the Bible had proclaimed that "in sorrow shalt thou bring forth children." But he came back with this riposte: That when Eve was created, God threw Adam into a deep sleep, and, taking one of his ribs, formed Eve. This was a silencer.

Although McDowell, an humble country doctor, performed successfully and almost unaided and alone, the operation of ovariotomy in 1809, no one had the courage to follow in his footsteps until into the '70's, when Sims, followed by the Atlees and (I think) Thompson of Harvard, made the abdominal cavity an open road to surgery. But it was some years before the surgeons, in the absence of soluble ligatures, ceased to clamp the stumps of the removed tumors outside the abdomen. The discovery of absorbable ligatures, and aseptic silk and other material, gradually did away with danger. I might here add that to Lawson Tait of England, we are greatly indebted for his teaching of asepsis, instead of antisepsis.

Then one brilliant discovery after another came within the compass of my medical life. Charles Louis Laveran, an obscure regimental surgeon in

* Read before the Placer County Medical Society.

the French Army, buried in the lonely sands of Africa, found the plasmodium malariae in the blood of malarial victims. For this he was hooted at, and belittled by the medical big-wigs of Paris, but "Truth is mighty and must prevail," and very soon his discovery was verified throughout the scientific world.

Then came Robert Koch, another obscure man, who demonstrated the whole life history of the TB, and so thorough was he, that he said practically the last word concerning it to this day. He also demonstrated the cholera spirillum, and he, too, was ridiculed by the "know-it-alls,' and Pettinkoffer, a celebrated German scientist, said he would undertake to swallow, and did swallow, a tube of cholera germs to prove the falsity of Koch's claims, and thereby nearly lost his life. After his recovery he was magnanimous enough to acknowledge Koch's discoveries, and to give him full honor therefor.

In 1885 Pasteur, one of the most brilliant men that ever lived, a chemist and not a physician, did the greatest thing for medicine that the nineteenth century witnessed. He demonstrated the immunizing treatment for rabies and inaugurated serumtherapy.

By the discovery of cells and germs, the microscope came into its own as an instrument of real scientific value. The stethoscope was just coming into general use, and I well remember my first one, used in my student days. It was turned out of one piece of cedar and about six inches long. Also I remember the first clinical thermometer used in the Montreal General Hospital. It was about sixteen inches long, fastened to a scale, with the end containing the mercury bent at a sharp angle so that it lay snugly in the axilla while the body of the instrument lay upon the breast of the recumbent patient. It was truly a fearful and wondrous instrument. Later in my time, instruments of precision came to aid the clinician—the sphygmograph, the sphygmomanometer, the counting chamber, the hematocrit, the hemaglobinometer and many lesser aids to medical science.

In the '90's came the era of the womb-slitters, made possible by the perfection of the speculum. There was a time when every doctor owning one of these instruments was slitting the cervix uteri for all female troubles. These were followed by the menders—with much language.

Next came one of the most important aids to the modern surgeon—the Roentgen Ray—or so-called X-Ray, discovered by Wilhelm Konrad Roentgen in 1895, which bares men's inner secrets. Radium followed in its footsteps. And so we progress.

Next I will speak of the fads and cults in medicine which have sprung up in my time. The Thompsonians, founded by Thompson, of Massachusetts, which afterward developed into the eclectic school, was just coming into vogue about the time I became a student.

The homeopathists, founded by Hahnemann in Germany, was attaining a hold upon the American public at the same time.

Next came osteopathy, founded in 1874 by Dr. A. T. Still.

Following this in the latter years of the century came Christian Science, evolved (by the much married Mary Baker Glover Patterson Eddy) from the foolish emanations of the addled brain of a paranoiac.

Next comes the natureopath, and then the crowning joke of all—the Chiropractor—who can cure typhoid fever, diphtheria, cancer, gonorrhea, syphilis, or any other old thing, with the chiropractic thrust. It is to laugh!

But, gentlemen, I see a better day coming. The Homeopaths now require almost, if not quite, as thorough a scientific training as the regular profession and are becoming as broad-minded as science can make them.

The Eclectics are also approaching nearer and nearer to us in their standards, and within another lifetime, like my own, will stand side by side with us. The Osteopaths also are requiring a better education and are demanding a thorough training in anatomy and physiology, especially, and will ultimately blend with us.

But the Christian Scientists and the Chiropractors are simply ulcers on medicine and must have their day, until they die out, which they undoubtedly will in the not too distant future. It costs nothing to become a Christian Science practitioner, and any waiter, farm-hand, laborer, etc., who can command $100 to buy a diploma, can become a Chiropractor.

The Serologists and Organotherapists should also be mentioned, as they have both got quite a standing, both in and out of the profession. Some of these theories have a real value, but most of them prove to be duds.

And now we are in the midst of the Endocrinologic craze and the era of Vitamines. We will spend a moment over these before closing. The latter class seems proven, although they do not yield their secrets to either the chemist or the microscopist, but they do their work! That is the point; selah.

But the Endocrinologist needs the hobbles of caution put upon his enthusiasm until much more research is made. The giant, the midget, the fat boy and the human skeleton are regarded now as victims to their own glands, and hopes are entertained that these processes can be controlled and the ancient mysteries of disease will be explained, so that what have been considered hopeless cases can be satisfactorily treated. But the realm of endocrinology has not been well explained as yet and the bold adventurer in its mazes is liable to become lost, or to do much damage to his fellow man. The conditions of the body that control these glands of internal secretion are still almost entirely unknown. As yet only two endocrine products are chemically known—thyroxin and epinephrin. The latter is very potent intravenously, but inert when swallowed. Until we know more about them all, we can not be sure that they are not altered or destroyed in the digestive canal. Therefore, why talk about Hormones? Again, to what degree is substitution therapy possible? Its value has been proved in thyroid deficiency, but it is useless in pancreatic diabetes.

Often the Organotherapist is justified by the

patient's expression of added well-being, or by disappearance of subjective symptoms—criteria of uncertain value. The facts should be faced that endocrine physiology is unproven, despite positive statements to the contrary. Every medical publication vaunts the use of some endocrine fad, even down to gland transplantation. Credulity rules mankind. "There is a sucker born every minute," it has been said, with, unfortunately, much truth. This opens the door for exploitation of the medical profession by charlatans, quacks and unscrupulous manufacturers. Medicine is humiliated by accepting, as gospel, every claim made with sufficient positiveness.

However, I do not wish to condemn endocrinology, nor to lessen the just claims that it has earned, but I do ask you for a proper scientific attitude toward the data that are advanced.

And now I have gone over my fifty-odd years in general practice, necessarily omitting many discoveries that have come to the saving of human life and well-being, during that period, and trying to keep down my own personality, but I can say with Virgil's hero, *"Pars fuit erat."*

Believing that our work is all the better for a little play, I will conclude with something in a lighter vein. I will give you a few verses written by myself on

THE OLD PRACTITIONER *

The old Doctor's getting older every year.
We watch his failing powers, year by year.
His step is growing slower;
His head is bowing lower,
And we note his lessening vigor, year by year.

His eyes are growing dimmer, year by year.
His legs are getting slimmer, year by year.
He has a tremble in his voice,
And his breath it makes more noise,
As he toddles down life's pathway, year by year.

His teeth are dropping out, year by year.
His false ones rattle about, year by year.
He mumbles at his food,
His digestion is not good,
And dyspepsia grips him harder, every year.

If you think he is down and whining, owing to years,
You've got another think a-coming, for this year.
For he's just as good at poker,
And the same old jolly joker;
He's a fighter from away back, through the years.

His mind is, maybe, duller, year by year.
But his experience is fuller, every year.
In his finger-end's an eye,
That your inner ills can spy,
And he makes better diagnoses, every year.

When the young men make their blunders, all the years,
The old cock stands by and wonders, year by year,
At the things they think they know,
That so surely are not so,
And knows that they'll grow wiser with each year.

So he's growing old and older, every year.
He sees his finish nearer, every year.
Gray hairs are getting thicker,
Has less capacity for licker,
And he's worse and worse a kicker, every year.

In his every fault we love him, through the years.
There are none that rank above him, in the years.
Soon the Lord will call upon him,
With his good and bad traits on him,
And he'll go to join his fathers for all the years.

* These verses were read before a few guests at a dinner in Coronado, some time ago, but never before published. (Rights reserved.)

The foregoing verses will apply to all of you, as pass the years.

INDUSTRIAL MEDICINE AND THE GENERAL PRACTITIONER *

By GAYLE G. MOSELEY, M. D., San Francisco

The treatment of industrial accident cases by the general practitioner has not proven satisfactory to either the physician or the insurance carrier. All of the causes of this dissatisfaction need not be considered at this time. The problem that presents itself for consideration is the bringing about of a better relation between the physicians and the insurance carriers, and securing co-operation instead of antagonism.

The general practitioner is an important factor in the furnishing of medical service to the large group of people covered by the Workmen's Compensation Law. The further trend of medical service in industrial accident cases will be largely determined by the attitude and the service rendered by the physician in general practice.

Whether or not industrial work will be more widely distributed or more centralized than it is at the present time, depends entirely upon whether or not the physician in general practice takes sufficient interest in these cases to give good service and furnish promptly the reports that are necessary for the insurance carriers to properly conduct their business.

If the doctor treating an industrial accident case will do three things he will rarely have cause for complaint.

First—Is to send full report of the accident promptly to the insurance carrier, as a doctor's report is the basis on which the case is handled, and is necessary before compensation can be paid.

Second—Not to attempt to continue to treat cases that should be in the hands of a specialist. All cases of eye injuries and severe fractures should be treated by specialists in those respective lines, and there is nothing that gives an insurance carrier a better opinion of a physician in general practice than to have him write in and suggest that a serious injury be placed in the hands of a specialist.

In private practice the physician does not hesitate to ask for consultation or refer a case to a specialist, but in industrial accident work a request for consultation is very rare. The physician that immediately refers serious cases to the insurance carrier inspires confidence, with the result that the insurance carrier will feel safe to leave any case in his hands, knowing that the doctor recognizes his limitations and can be depended upon to act accordingly.

Third—Is to send in a bill for services rendered. If this is sent in according to the established fee schedule, being careful to note on the bill the reasons for any unusual charge, or charge in excess of that allowed by the fee schedule, the bill should be paid promptly.

The physician should be extemely careful, however, to make out his bill strictly according to the fee schedule, as the medical expense is a fixed amount, being a definite proportion of the premium collected for each risk.

* Read before the Section on Industrial Medicine of the Medical Society of California, Yosemite National Park, May 15, 1922.

If the medical expense is in excess of the allowance provided by the rates on that particular risk, the business immediately becomes unprofitable. Because of the fact that some think that the fees allowed for treatment of industrial accident cases are too small, there has been a tendency to take advantage of the fee schedule and make charges for unusual amount of time and dressings. Sometimes on examining X-rays that were not extremely clear, the physician has been able to see a chipped bone or a slight discoloration, where further X-rays showed a normal condition.

The expense of physiotherapy is another item which gives promise of causing trouble between the physicians and the insurance carriers. Physiotherapy is necessary and helpful in many cases, but should not be used as a means of increasing the medical expense in industrial cases.

The medical cost in workmen's compensation insurance is an economic problem, and the organized medical profession should co-operate with the insurance carriers to make this expense as reasonable as possible, and at the same time be fair to all parties concerned.

The first consideration must always be service to the injured employe, and the profession should go on record as favoring better service for industrial cases, just as they have gone on record for the betterment of hospitals.

In case of a controversy arising as to the amount of a medical bill, or any other question with reference to an industrial accident case, the matter should be promptly referred to the office of the State Medical Society, and their opinion or ruling should be cheerfully accepted by the physician. The establishment by the society of a department to arbitrate matters with reference to industrial practice, is the first real constructive work that has been accomplished by the medical profession since the passage of the Workmen's Compensation Law.

If the individual physician will work in harmony with the medical society and not be influenced by a few whose main mission in life seems to be to stir up strife between the physicians and insurance carriers, many of the troubles and misunderstandings will be a thing of the past.

(333 Pine street.)

Putting "Jazz" into Medical Book Publishing—Some of the advertising and propaganda methods of some of the medical publishing houses may be read best to the tune of a "jazz" orchestra. They read like an advertisement of "Yeast," "vitamins," "pink pills" or the "miracle man." They appeal to the cupidity of the physician, and they claim to be "new stuff," which probably accurately describes many of the books which physicians are asked to buy and consider as authoritative. In answer to many questions from physicians about the value of various books, the Journal makes two suggestions to our members: Don't bother about a book that is advertised by the "direct-by-mail" method, and don't bother about one until you have seen a number of reviews of it in medical journals, whose review pages are not influenced by a "complimentary copy."

PHYSIOTHERAPY IN THE TREATMENT OF THE CHILD WITH RHEUMATIC FEVER *

By EDITH BRONSON, M. D., San Francisco

Children suffering from the rheumatic cycle of affections, acute arthritis, carditis, and chorea, occupy a number of days of hospital beds disproportionate to the actual number of such cases admitted. After a period of acute illness, many a child ceases to improve and settles into an invalid state. Nutrition and musculature degenerate, and of even more importance, the weariness of discouragement is added to the actual physical disability. The unconscious attitude of the physician to the chronic cardiac is too well registered on the sensitive nervous system of the child. Finally a bed can no longer be spared, the child is allowed to sit up, perhaps walk about, and is sent home, physically incapacitated and mentally discouraged.

The purpose of this paper is to report an effort to shorten the hospital stay of the rheumatic child, to prevent the physical disability of prolonged confinement in bed, and to have the patient leave the hospital in posture and general physique, superior to the average untrained healthy child. Finally we have been attempting to help the child to remain keen to improve, during the difficult adjustment stage in his own home.

In the treatment of acute cardiac disease, too often we can not prevent impaired function in the heart itself. Healing in damaged valves and muscles, as healing elsewhere in the body, takes place by fibrosis, and the presence of non-elastic fibrous tissue in an organ whose function depends in a peculiar degree on the elasticity of its muscle, causes an unavoidable permanent injury. We have escaped from the interpretation of the functional disability following such injury, by the presence of the signs of valvulitis. The function of the heart as a whole is being studied. Gradually we are beginning, I may better say returning, to the study of both the pathology and function in an organ in its relation to the physiology of the individual as a whole, and to his adjustment as a member of society. Of the greatest importance it is, that we consider in the physiology of the circulation, the interchanging balance between circulatory, respiratory, metabolic, and nervous systems. What physiotherapy attempts to do is to preserve and increase the usefulness of these compensating functions.

In whatever ailment, physical treatment may be applied, whether to postural defects, or to cardiac insufficiency, the principles for success remain the same, and for them we have to thank the experimental physiologist. An attempt to treat cardiac injury in itself by physical methods, would be like attempting to treat acute rickets by putting plaster casts on the child's legs. For success the individual as a whole must be the object of therapy.

Probably each observing physician has developed a method of his own for estimating cardiac effi-

---

* Read before the Pediatrics Section of the Medical Society of California at Yosemite National Park, May 17, 1922.

ciency, but we live in an age of classification and standardization. Exact measurements are taking the place of clinical opinion. Efficiency tests, the significance of the measurements of the vital capacity, the interpretation of changes in pulse and blood pressure, are being studied in cardiac clinics. If such methods are used to develop clinical judgment, the patient will be better cared for. There is a danger that, as the results of researches are standardized, the standard will be applied without due regard to the individual patient, and will increase the present tendency to turn the physician into an expert manipulator of machines. Tests of function and methods of treatment are of value to the patient only when utilized with observing and sympathetic judgment.

I have made these digressions upon the subject to which I am assigned, partly to justify myself for the rather narrow outlook which I may seem to take in the actual work which I am reporting.

By carefully graded exercises we have been able to shorten the hospital stay, and improve the exercise tolerance of cardiac children. An outline of the method of treatment which we have gradually evolved is presented below.

PHYSIOTHERAPY IN THE TREATMENT OF CHILDREN WITH RHEUMATIC FEVER

CARDITIS

First Stage (10 minutes twice daily)—To be started as soon as pain subsides:

1. Effleurage to arms and legs.
2. Teach **correct** breathing. When possible include abdominal massage for five minutes.

Second Stage (20 to 25 minutes daily)

1. Effleurage and light petrissage (to extremeties and back or abdomen).
2. Passive arm movements with breathing.
3. Passive leg movements—gradually adding active ankle and knee flexion and extension.

Each exercise to be done from three to five times.

When possible increase active work. Do one arm, including exercises, before massaging the next. In bad cases do arm, then leg.

Third Stage (30 to 40 minutes daily)

1. Massage (medium) general.
   (a) Effleurage, petrissage, friction, tapotement.
2. Light resistive and increase gradually.

Exercise given for every joint movement and each exercise repeated three to eight times.

3. Deep breathing.

Fourth Stage (40 to 45 minutes daily)

1. Active exercises in bed.
2. Start standing—**teach posture.**
3. Heel raisings, arm exercises with breathing for a couple of days, then add trunk bendings and twistings and leg exercises gradually increasing at the rate of one to two daily.

Fifth Stage (45 to 60 minutes daily. According to age and strength of child)

1. Vigorous exercise, including stair climbing, running and jumping.

CHOREA

First Stage—To start immediately on admission to hospital:

1. Effleurage to extremities and back or abdomen.
2. Teach breathing as soon as possible.

Second Stage

1. Effleurage and light petrissage (to extremities and back or abdomen).
2. Passive movements combined with breathing.
3. Assistive, active exercises.
   (a) For co-ordination.
   (b) For re-education.
   (c) For rhythm.

Third Stage

1. Massage (medium) general (no tapotement).
2. Active exercises with breathing.
3. Active exercises especially for back (assisted at first).
   (a) For co-ordination.
   (b) For re-education.
   (c) For rhythm.
4. Chorea tests.
5. Singing vowel sounds.

Fourth Stage

1. Active exercises in bed.
2. Start standing, **teach posture.** Begin with easy exercises and gradually increase, not allowing an unassisted movement until child has balance and confidence.
3. Continue 4, 5 and 6 of Stage Three.

Fifth Stage

1. Vigorous gymnastics. Prepare to go home.

We have tried to make the system as elastic as possible. A "stage" may last less than a week or several weeks, according to the condition of the patient. Again, we have not been able to state definitely when physiotherapy should start. In the type of rheumatic fever in which a high temperature and an acute arthritis subside rapidly under treatment, the first stage of physiotherapy is started as soon as the pain and swelling have disappeared. If, however, we should always wait until there were no rise in temperature, we should deprive of massage and passive exercise, the type of cardiac child who has at no time a high fever or acute arthritis, but who for months may run a low grade septic temperature curve—the subacute chronic rheumatic child. Such a patient is in the greatest need of physical training. On the other hand, a child with no rise in temperature may be suffering from a degree of cardiac failure which may contraindicate the gentlest of massage. Clinical judgment must be used as to when to start physiotherapy, as well as when to pass from one stage to the next.

During the first three stages the patient is carefully protected from exertion of any kind except that which accompanies the exercises. He is fed by the nurse and encouraged to do nothing for himself. It is a well recognized fact that the ordinary routine of work, for example, that of the housewife, brings weariness without giving training to the physiological functions. The training of the athlete is accomplished by increasingly severe muscular exertion interposed with periods of complete relaxation. Co-ordination of respiration with muscular contractions is imperfect in the untrained individual as contrasted with the trained. The training of the cardiac child is essentially the same as that of the athlete. He is first of all taught relaxation, taught how to rest, taught how to breath as a means of improving his vital capacity, and how to breathe rhythmically with the passive arm and leg movements which

are gradually added. In passive movements attention is given to counteract the tendency to tendon tightening which is so frequently a sequence in all chronic illnesses. The length of the period of exercise is increased gradually, as well as the degree of work. By the end of the third stage the type of massage has become vigorous, especially to the abdomen and back. Friction and tapotement as used probably produce tendon and muscle relaxation not unlike that secured by certain of the cults in their manipulations. Resistive now take the place of passive exercises. These require voluntary effort, yet effort which is under the control of the technician. Though by the end of the third stage, it is not infrequent to have produced muscular hypertrophy, the predominating effort has been to teach relaxation and co-ordination.

The pulse, respiration and systolic pressure are taken daily by the technician, before and after exercise, and again in two minutes. Once weekly the physician is present throughout the period of treatment taking the systolic blood pressure to note the type of curve, and to make observations on the child's general reaction. Up to the end of the third stage, rarely does the pulse increase more than fifteen or the systolic blood pressure rise more than ten millimeters of mercury.

By the fourth stage active exercises for arms, legs, back and abdomen are substituted for resistive. These are interposed with short periods of breathing. The child has now learned rhythmical breathing. He begins to stand and is taught first of all, posture. A correction of postural defects has been emphasized throughout the previous stages. Probably no other word has this importance in physiotherapy. Postural training not only increases the vital capacity, diaphragmatic contraction and expansion, but it has a very definite relationship to the functional nervous system of the child. Setting up exercises develop "backbone" as well as muscle.

The fifth stage is a preparation for the activities of home life. The attention to posture and breathing is carried into such exercise as climbing stairs and running and jumping. The ideal is to have the child leave the hospital a trained individual, able to do the routine work of his childhood with co-ordinated and not wasted effort.

Not all children with corditis ever reach the degree of physical well-being which I have pictured. Those unfortunates who, after months of illness, are left with a developing stenosis, damaged muscle, and adherent pericardium, may pass their lives, usually of only a few years, unable to perform the equivalent of our fifth stage of exercises. Even in these crippled children, the trained use of the compensatory functions has surprised us in the results obtained. With the co-operation of intelligent parents these children, leaving the hospital able to take only the third stage of exercise, may continue to improve so that they can carry the burden of school life, and in a narrowed sphere, lead a useful existence. Reinfection, rather than over-exertion, is to be dreaded. Their course of training has taught them when they should rest, as well as how to make the ordinary duties of life exercise, rather than work. Our failures have been from environment adjustment, rather than the actual condition of the child. The crying need for such children is a cardiac convalescent home. After a period of hospital care improvement may cease. Children with acute illnesses come and go, the cardiac child remains. Unless his own home is exceptional such a child should continue his treatment in a home with his own kind, with games and school suited to his endurance. As a problem of preventive medicine, the rheumatic cycle child needs the same careful study as the child from a tuberculous environment.

I have used the title "Rheumatic Fever" advisedly, so as to include that manifestation of the rheumatic cycle called chorea. If chorea is associated with arthritis and carditis, the treatment is the same as for these with the addition of special co-ordination and educative exercises. In uncomplicated chorea treatment starts the day following admission to the hospital. The usual routine of quiet and isolation is enforced. No sitting up is allowed, no book or plaything. The teaching of relaxation is especially valuable here and assistive movements controlled by the technician give the child confidence. So far as I have been able to observe, no specific cure, such as is not infrequently seen, if some acute illness like influenza or measles intervenes in the acute stage, has followed physiotherapy. However, in rather frequent instances, a time comes when chorea as an "infection" has passed, but the "habit" of chorea remains. In such cases the work of the physiotherapist in re-education, is of inestimable value. The ideal would be for a full-time technician for each child, to assist in his play, at his dinner, and in all the ordinary duties the performance of which he must relearn.

In conclusion, we are able to state that after even severe rheumatic infection, a child wisely treated by physiotherapy reaches the stage of convalescence with a posture and muscular development superior to that previous to his illness, and that he leaves the hospital physically trained to use to the best advantage the functions compensatory to his cardiac injury.

I have to thank Miss Boville, physiotherapist, for her enthusiastic co-operation in this work.

(240 Stockton street.)

Rejuvenating Roués—In a recent Sunday edition of a California paper, in a department advocating free organ recitals, religious ceremonies and fakes, we find under prominent display some more purported news about how old broken-down roués may be restored to youth, and even how their white hair may resume the color of youth and their wrinkles fill out under the skin under the latest goat gland operation. The article in question indicates that it is a Universal Service report from London. It takes up a further exploitation of "Professor" Steinach's operation. The article goes on to say that "Professor" Steinach is kept busy rejuvenating elderly men and women. It states that after the operation "white hair turns to its natural color, wrinkles fill out and take on fresh color." Further quotation from this article is: "In England interest in the rejuvenation craze subsided about the beginning of the year, when an old man who returned from Paris after treatment died on the day he was announced to give a lecture on his recovery of youth." ? ? ? ?

TRAFFICKING WITH HEALTH

(Considered and approved for publication by the Council of the State Society, September 8, 1922)

The time has come for some plain speaking. On November 7 the citizens, or more correctly the voters of California, are going to decide the character of medical education, medical practice, hospital service and public health regulation, they wish applied to themselves and their children during at least the next few years. They are going to decide whether education or ignorance shall be the standard under which they will protect the health and welfare of their families. They will determine whether adequately educated law-abiding citizens shall treat them when they are ill, advise them in methods to protect themselves and their families against the invasion of contagion and pestilence, or whether these services are to be relegated to the uneducated, or to the lawless, or to those anti-health charlatans who are openly and flagrantly attacking the standards of experience and education that have been built up through the ages.

We do not believe the time has come when the educated physician must apologize for being educated, or perchance take his orders and laws from ignorant or inadequately educated cultists as health officers, directors of hospitals, and as heads of educational institutions. Should lawlessness and ignorance win in the November election, there will be no legal excuse to maintain the great medical schools of the University of California, of Stanford University, or of the College of Medical Evangelists—the three principal sources of supply of California physicians of the future. These three schools cost the people of the State more than two million dollars a year, and one of the arguments made by some of these cultists is that most of this money could be saved.

Should they win there will be no reason for continuance of the State and municipal health boards nor for health and quarantine laws based upon scientific knowledge of the nature and spread of disease, and enforced for the protection of man and animals. These cultists do not believe in scientific bacteriology or the proven causes and courses of disease. All of the twenty-seven varieties are based upon disproved, unsound theories without a foundation in fact. Some of their fundamental claims are based upon false conceptions of the elementary facts of anatomy and physiology.

The various cults have about thirty so-called schools and colleges in California claiming to prepare students to teach and to practice the healing art. Did you ever see one of these schools? Do you know what they teach; how much; and for how long; and what the actual entrance requirements for students are? Did you ever examine a list of the faculty of one of these schools and compare it with existing educational university standards? If you are an interested citizen, you should do some of these things.

If all the legitimate assets and all of the equipment of all of these schools were combined, they would not have enough to fulfill the legitimate requirements of one school adequately equipped to prepare students to diagnose disease, and discuss and practice the healing art upon an adequate scientific basis. Some commercialized quacks are openly attempting to get charge of the hospitals of the State because, as they assert, with the application of their Science (?) to the patients, the hospitals would soon be empty and much of the millions of dollars they are costing would be saved the taxpayers.

Some people, including a few physicians, health officers and educational officers, profess not to see the dangers in this situation. They are imitating the ostrich, and a very few have allowed their cupidity to obscure their ideals and befog their intelligence. A very few physicians are heard to say, "Why bother about the Chiropractors and the Osteopaths? The more cultists there are, the more business *in the end* for physicians." Thank God, there are but few such in our ranks. When you find one, examine carefully and you will find him connubiating with cultist "runners" or you will find a man whose ideals, ethics, love of his profession and of mankind have turned to brass and tinkle like a cymbal. For over a year and at the present moment certain of these cultists are making strenuous efforts, backed by the power of their political machine and by exhaustive and expensive advertising propaganda, to get on the staffs of hospitals, and their greatest efforts are to control the State, county and municipal institutions. These institutions are considered more vulnerable because, in most instances, they are administered by government officers, sometimes susceptible to political influence. They aim to get in by political power just as they aim to have education legislated into them and a license to practice placed in their hands. If they win in the forthcoming election, why not?

They already have students from among our disabled veterans of the World War studying (?) in their colleges (?) and their tuition being paid for out of your taxes. One of these so-called schools has more government students than have all the legitimate medical schools of California.

The physician who can view the efforts of cultists of one kind and another to destroy the standards of medical education, the practice of medicine and public health without using every effort to combat their activities, forgets his duties as a citizen and misinterprets the greatest function of the true physician. During epidemics the physician works overtime to instruct his patients and friends in the methods of prevention. These organized cults are more menacing to the public health than an epidemic. We may differ in opinions as to the best methods to counteract this menace, but we cannot evade the responsibility of doing our best, both as physicians and as citizens, to protect our fellow citizens against it.

The League for the Conservation of Public Health, by delegation the Section on Medical Economics, Hospitals and Public Health of our State Society, is recognized as our representative

in these matters. Some of their arguments and suggestions are published in this number of the Journal. These and others to be furnished later, as well as the campaign of education proposed by the League, have the unanimous approval of the Council of the State Society. The Council requests all physicians, hospitals and medical agencies to do their duty under the leadership of the League, with the understanding that our campaign is for the betterment of the health of the citizens of the State, and is for the good of us all as citizens.

Physicians and Hospitals of California: In the interests of public health and safety, urge the citizens of your communities to vote No on Anti-Health and Anti-Education initiatives, numbers 16, 20 and 28.

PHYSICIAN OR SANITARIAN?

(Considered and approved for publication by the Council of the State Society, September 8, 1922)

Under this title and commenting upon the report of Mr. George E. Vincent, president of the Rockefeller Foundation for 1921, we read in the editorial column of "Current Opinion," September, 1922:

"The fundamental delusion of the medical profession is that it makes a living from diseases. It studies diseases. The library of disease is enormous. But the real scientific approach to the problem of human welfare is through the study of health and the prevention of diseases. The sanitarian, after all, is a more important advance agent for the millennium than the physician."

This quotation is worth reading again. Press clipping bureaus bring large numbers of other comments that go much farther than this. And where is this one going? Read it again. It is statements of this character and the report of the character of Vincent's that is helping the chiropractors and other cultists, working from another angle, to convince the uninformed people of this country that educated physicians, trained in pathology and in the diagnosis and treatment of disease, are little better than artisans, secondary in importance to the newly created "sanitarian." It ought not to be necessary to belittle the physician nor the methods of his training in order to create a new specialist who, after all, at his best is only a physician. Everyone will applaud legitimate efforts to improve the preventive medical work and the saving of suffering by disease and the prolongation of life. This always has been and is considered by every physician one of his most important functions. It is also a function that never has been discharged and never will be discharged effectively for the great mass of people in any other way than by the physician who is trained in the sciences, arts and humanities necessary for effective work in his field. If the people who are interested in developing public health at the expense of physicians succeed in reaching their goal, what is going to become of the twenty to thirty million people who are sick every year in the United States? The millennium, as propounded by Vincent and other lay doctors, when our efforts and money will be devoted principally to the prevention of illness because there will not be any illness, is a long way off, and it is doubtful whether anything more than a very short step has been taken during the last decade in the direction of that millennium.

FOLLOWING FALSE GODS

(Considered and approved for publication by the Council of the State Society, September 8, 1922)

Physicians of California are getting pretty much "fed up" on itinerant medical evangelists from "the East." Some so-called "Big Men" of our profession find the sphere of their influence too much cramped by their own territory. By proper angling they secure invitations from organizations in California and other western States and make the circuit periodically. In many instances they come preaching medical and public health socialism and usually they are personal propagandists of a familiar species. Their audiences in California are of the same general classes as their followers back home.

There is a serious side to their activities. They influence a certain element, particularly among the younger and more inexperienced physicians, and they are the final authority for lay doctors and uplifters, because socialistic theories are always appealing. The majority of these specialists are opposed to policies of the medical profession, and openly advocate movements that are calculated to make physicians assistants to or "co-operators" with, the self-constituted lay leaders of medical and public health practice.

One of these physicians is reported to have said recently, in effect, that medical social workers should align themselves with the lay social movements and avoid too close contact with the medical profession. Another one has been preaching the same general principle to public health nurses, medical social workers and other technicians. Most of them think much of the title of sanitarian and belittle the physician who is only an M. D. These men usually are quite successful as publicity agents for themselves, and when they are about, the press acts as if the discoverer of a new cancer or tuberculosis cure had just arrived direct from Vienna and the ether waves from the broadcasting stations D. O. and D. C. dance with delight.

The climate of California seems to stimulate these medical evangelists and personal profiteers, and their froth bubbles away faster than it does even in their home towns. It is fortunate for some of them that physicians of the Golden West have a sense of humor.

SUBSIDIZING CULTISM

(Considered and approved for publication by the Council of the State Society, September 8, 1922)

Subsidy constitutes one of the best methods of control of any movement, organization, method or person. It is probably the third most effective of all methods of control, the other two being direct financial control and political control.

All of these methods are extensively applied in medical and public health matters. They are all being extended rapidly in all things medical. It is difficult to say which will prove the most disastrous in the long run—political or subsidy control. It was formerly quite generally thought that noth-

ing could be worse than political control, but with the phenomenal spread of subsidy control of medical education, medical practice and public health into the hands of a few men representing Foundations, and as the dangers of this method become more palpably apparent, many are beginning to wonder what the end will be.

Many organizations, institutions and movements have cheerfully invited subsidy and are continuing to do so without looking beyond the immediate future.

Some recent developments in the gilded fields of subsidy are likely to focus attention on the whole problem. In several instances, misguided philanthropists have offered generous subsidies to institutions in California under the conditions that they provide departments for some cult. We do not know of an instance where such throttling conditions have been accepted. The offers in some instances have attractive coatings designed to deceive. Donations and subsidies look attractive, but in both instances it is well to look carefully at the "strings" before accepting one.

THE HOSPITAL CONVENTION

The Second Annual Convention of the Hospitals of California was held at the Maryland Hotel, Pasadena, September 5, 6, 7 and 8, under the auspices of the League for the Conservation of Public Health. The slogan of the convention was that of the hospital betterment work of the League

"To promote and maintain more and better hospitals wherein educated physicians may render better service to every citizen of every community of California."

From whatever angle viewed, the convention was a striking success. Over three hundred hospitals were represented by over eight hundred delegates and other interested persons. The program as printed was carried out with but few minor changes, and the audience remained intensely interested and even enthusiastic throughout the four days of almost constant discussion. The policy initiated last year at the First Annual Convention was maintained, by which written papers were avoided and the discussion of problems of vital interest to hospital people was substituted.

Both the commercial and scientific exhibits of the convention were of a very high order, instructive and useful.

A number of important resolutions were passed and these, together with a full discussion of the convention, will be published in full in the next number of "Better Health."

The Council of the State Medical Society held two meetings at the same time and place, and there was one meeting of the Council with the officers of the various county medical societies and the section officers of the State Society.

THE ENLARGED JOURNAL

With this issue the JOURNAL enters another stage of development by the addition of 16 more pages, thus increasing the size from 100 pages to 116 pages. This improvement has been made possible by increased advertising and increased subscriptions. Suggestions for further improvement are invited from members and subscribers.

Are Physicians Required to Report All Accidents to the Industrial Accident Commission? (Opinion by Hartley F. Peart, Chief Counsel State Medical Society.)—Some time ago physicians were informed by the Industrial Accident Commission that they were required by law to report all accidents attended by them to the Commission. The Council of the State Society asked Chief Counsel Peart for an opinion as to the legal right of the Industrial Accident Commission to impose this extra work on physicians. Mr. Peart's opinion is as follows:

"Referring to your request for an opinion as to whether or not the Industrial Accident Commission of California is authorized by law to require physicians to report the details of all accident cases which they may be called upon to attend, I beg to advise:

"That Section 21 of the Constitution as amended November 5, 1918, authorizes the Legislature to create and enforce a complete system of workmen's compensation and to create and enforce liability on the part of all persons to compensate any of their workmen for injury or disability incurred or sustained by the workmen in the course of their employment.

"Pursuant to such constitutional authorization the Legislature has passed various Acts. The present Workmen's Compensation, Insurance and Safety Act in its introductory section states that it is intended to make effective and supply a complete system of workmen's compensation, using substantially the language of the Constitution in reference to injuries and disabilities 'incurred by employes in the course of their employment.'

"'Injury' as used in the Act is defined to mean any injury or disease arising out of the employment.

"The compensation provisions of the Act refer to any injury sustained by the employe arising out of and in the course of the employment, and it is clear that the injuries and disabilities referred to in the Constitution and the Statute are only those of employes in the course of their employment.

"In Section 16 of the Act it is provided that 'any physician who shall make or be present at any such examination (an examination where the right to compensation exists in favor of any employe) may be required to report or testify as to the results thereof.

"In Section 19 relating to evidence, it is provided that in the case of the death of an employe 'the Commission may require an autopsy, and the report of the physician performing such autopsy may be received in evidence.'

"Under the safety provisions of the Act and in Section 53A, it is provided that 'every employer of labor, without any exception, and every insurance carrier and every physician or surgeon who attends any injured employes, is required to file with the Commission under such rules and regulations as the Commission may from time to time make a full and complete report of all injuries to an employe arising out of or in the course of his employment,' etc.

"From the foregoing, I conclude that the Commission is not authorized by law to require reports of physicians and surgeons as to every case of accidental injuries or accidental death, which a physician or surgeon may attend. If the circumstances were such as to raise the question as to whether or not the person so attended was injured or killed in the course of employment, then a report should be made promptly, but your question as I understand it, is based upon a blanket notice addressed by the Commission to all physicians requiring them to report fully on all accident cases attended by them. In my opinion, the Commission has not the authority to require such universal reports, in all accident cases for the reasons above stated."

20	*NO. 20. Osteopathic Anti-Health Initiative.* Creates another Special State Board of Examiners composed Exclusively of Osteopaths for special interests of osteophatic colleges and graduates; comically calls itself "self-sustaining" whilst imposing many additional duties on state, county and municipal offices that necessarily create expenses which taxpayers must meet; provides very quick but very dangerous way to make physicians and surgeons of osteophatic graduates who fail to pass present easy State Examinations; grants Board perilous power to license drugless osteopaths to administer narcotics and attempt most serious surgical operations; nullifies present State laws which forbid ostepaths from administering opium, cocaine, morphine and other habit-forming drugs. Vote "No."	Yes	
		No	X

Education Cannot Be Voted Into Them

Two years ago the people of California defeated the osteopathic referendum by a majority of 209,000. This overwhelming verdict of the people emphatically endorsed the law prohibiting osteopaths from prescribing narcotics.

The California Legislature rejected the Osteopathic Act by a two-thirds majority after investigating the absurd accusations of "medical tyranny, injustice and incompetency" made by osteopathic partisans. This osteopathic act is a "misnomer." It has practically nothing to do with osteopathy. It is self-contradictory and wholly at variance with the well-settled definitions of osteopathy in Court decisions, in dictionaries and in osteopathic literature. In co-operation with the other two members of "The Obtuse Triangle" it would create two new Boards of Medical Examiners in California which would divide and confuse the licensing and regulation of physicians and surgeons and drugless practitioners.

It nullifies essential jurisdiction, duties and functions of the present State Board, repeals vital public health safeguards and educational requirements and grants a Board of Five Drugless Osteopaths the inconsistent and dangerous power of licensing osteopathic graduates, without adequate training and education, as physicians and surgeons.

Under the loose terms of this Osteopathic Act, all graduates of osteopathic schools and drugless practitioners graduated from osteopathic schools may be licensed as physicians and surgeons. This offers a very quick but a very dangerous way to make physicians and surgeons.

Osteopaths and Chiropractors base their demand for Special Boards on the erroneous claim that each has discovered "a complete system of healing." Chiropractic IS what osteopathy WAS. We must conclude that the failure of osteopaths and chiropractors to build and conduct hospitals in California is because hospitals form no part of their alleged "Complete Systems."

No physician and surgeon can be properly prepared without adequate hospital training. A little learning is a dangerous thing. Graduates of alleged "complete systems" with incomplete education menace public health.

What IS Osteopathy?

The Supreme Court of California decided: "License to practice osteopathy should not be deemed to authorize the practice of medicine and surgery—requirements for a license to practice osteopathy and for a physician's and surgeon's license have always been different." Another Supreme Court decision says: "Osteopathy administers no drugs; it uses no knife." The Standard Dictionary defines osteopathy: "The treatment of disease without drugs or knife . . ." The Society for the Advancement of Osteopathy says: "Osteopathy is the original science of spinal adjustment." The founder of osteopathy, Dr. A. T. Still, declares, "We are opposed to the use of drugs."

Since 1901 osteopaths have been examined and licensed to practice their drugless method in California. Any osteopathic or other drugless practitioner who has adequate education can now secure a physician and surgeon certificate by passing the higher examination required for physicians and surgeons. During the past eight years 48% of the graduates of osteopathic schools who have taken this examination have failed to pass. In impressive contrast—100% of the graduates of the University of California, of Stanford and the College of Medical Evangelists have passed.

If thousands of untrained "48% graduates" with no hospital preparation or surgical experience are turned loose in California with the unlimited license to prescribe the most dangerous drugs and perform the most serious surgical operations, the damage they can do is immeasurable.

The "48% graduates" need more education, not more Examining Boards. Education can not be voted into them.

Vote "NO" on Anti-Education Initiatives Nos. 16, 20, 28.

COUNTY NEWS

ALAMEDA COUNTY

Del Valle Farm for Tubercular Children—This health farm is operated by a board of directors of which Miss Annie Florence Brown of Oakland is president. Miss Lillian O'Neill, a nurse, is the executive officer. A movement is on foot to further develop this farm and bring it in as a unit of the Alameda County consolidated health program.

FRESNO COUNTY

Fresno County Medical Society (reported by Thomas F. Madden, secretary)—The regular meeting of the Fresno County Medical Society was held at the Commercial Club September 5, 1922. The following members were present: Miller, Tillman, Cross, Montgomery, Aller, J. R. Walker, Kjaerbye, Brown, Pettis, Bell, Sciaroni, Goldberg, Schottstaedt, Mitchell, James, Konigmacher, Trowbridge, Ehlers, Avery, Broemser, Jamgotchian, Milholland, Webster, G. W. Walker and Madden.

James E. Pendergrass of Clovis and Yervant Minas of Fresno were elected to membership.

Frank Hinman of San Francisco discussed "Tumors of the Kidney and Testes." Cross and Konigmacher also discussed the subject.

W. W. Cross, G. W. Walker, D. H. Trowbridge and Thomas F. Madden attended the meetings of State and County Society officers at the Maryland Hotel at Pasadena on September 8 and 9.

Regular meetings of the staff of the Fresno County Hospital were resumed on September 12. Luncheons of the surgical and medical staffs were also resumed.

Guy Manson returned September 6 from a visit to the clinics at Chicago. C. O. Mitchell spent the month of July at the Johns Hopkins Hospital in post-graduate work.

County Hospital Annual Report—The report of this hospital shows progress during the year. A school of nursing has been established. The students secure their academic work from the Junior College of Fresno. A staff has been appointed and organized into departments. The general staff meets once a month and the various departmental staffs each once a month. The report shows the total cost of operating the hospital for the year to have been $266,253.22 or $2.20 per "patient day." The average cost of meals was 19 cents each. There were 139 births and 275 deaths in the hospital. The number of autopsies is not included in this report. Average daily census of patients was 272 or a grand total of 99,280 "patient days."

KINGS COUNTY

Public Health Progresses in Hanford—Hanford has a new health officer in Dr. Albert G. Bower, who took office July 1. Dr. Bower, who has had considerable public health experience in the Army, is an enthusiastic organizer and he is working zealously for the development of a full-time health department in Hanford.

LOS ANGELES COUNTY

New Medical Teaching Center Contemplated—It is reported that the $10,000,000 campaign of the University of Southern California is receiving hearty support. Plans for the use of these funds include provision for a medical school and teaching hospital at a cost of $3,500,000. Dr. Wesley W. Beckett, member of the board of trustees of the University is quoted as saying that there is no place in the United States so far removed from a medical school as Los Angeles.

California Lutheran Hospital—It is reported that this hospital will shortly begin the construction of a nurses' home to cost approximately $250,000. The Anita M. Baldwin Clinic for Children building as part of the hospital has just been completed.

Pasadena Requires Examination of Food Handlers—During the month of July more than 550 food handlers were examined in the Pasadena City Health Department in accordance with the requirements of a local ordinance. Pasadena is the only city in California which requires that all handlers of foodstuffs must pass a satisfactory physicial examination, showing that they are not suffering from communicable diseases.

Pasadena Preventorium—This new venture is located on an eight and one-half acre tract of land. The building is to cost $35,000 and is to be erected shortly. The Preventorium will be incorporated under the laws of the State and will be conducted by the management of the Pasadena Dispensary. Mrs. Irving Sturgis is president of the organization.

MONTEREY COUNTY

New Hospital for Salinas—The Red Cross Health Center property at Salinas, Monterey County, has been sold to a group of physicians and will be converted into a hospital in the near future. Doctors E. W. and W. H. Bingaman of King City, A. S. Lineer of Soledad, W. Rollin Reeves, Edwin W. Reeves, D. B. Wylie, T. C. Edwards and J. A. Beck of Salinas, are the prime movers in this new enterprise.

ORANGE COUNTY

Santa Ana Hospital—Mr. A. B. Wastell has been engaged to do the promotion and organization work for the new Santa Ana Hospital. Mr. Wastell has just successfully completed a similar service for the people of San Jose and the San Jose Hospital is well on the road to completion.

RIVERSIDE COUNTY

Riverside Community Hospital—Mr. L. B. Saunders, formerly of Baltimore, has been appointed director of the hospital and is now on duty.

SACRAMENTO COUNTY

Flitcroft Hospital—It is reported that a new twenty-room hospital, located at 3014 M street, Sacramento, will shortly be completed by Arthur Flitcroft. The hospital is all concrete and brick construction and is being fitted up especially for maternity and surgical cases. The site for building represents an investment of $50,000. According to the report, it will be ready for patients in October.

SAN FRANCISCO COUNTY

San Francisco County Medical Society—Presentation of a portrait of the late Dr. Harry M. Sherman to the San Francisco County Medical Society (by his widow, Mrs. Sherman); address of acceptance by Douglas W. Montgomery, M. D.—Through the thoughtfulness of Mrs. Sherman we are presented tonight with an excellent portrait of her husband, the late Harry M. Sherman, so many years an honored member of our Society. The gift was accompanid with the request that it be hung beside that of his friend, George Chismore. And indeed, this is most appropriate and typifies a long and close friendship between two men having like professional ideals and like democratic views of government, and of social equality before the law, and who carried into their everyday life these same principles of fairness and justice, both to themselves and to their neighbors.

Sometimes, like a flash of lightning, a look or gesture will illuminate the relationship between two men. One day I happened to enter Chismore's room with Sherman. Chismore, who suffered a long, trying illness before his death, was in a reclining chair with that look of beatitude and peace which so transforms some elderly people. Sherman kissed the old man on the forehead, and the return look of affection I shall never forget.

As I went away, I reflected that these two men had known one another intimately for years, and in fact, had grown old together. A friendship such as evinced by them could only be the result of a mutual esteem, resting on honest, solid traits of character, which are only too infrequently met with in this rude world.

It is indeed sweet and commendable to give these mourning duties, which we are here this evening to fulfill, to one who throughout his active life never ceased to take a deep interest in the affairs of this Society. He, together with Philip Mills Jones and Dudley Tait, did more than any others to develop its ethical side, and to make the Society what it is, and to set it on its road for what it may become.

While industrious in developing the form and government of the Society he also was not slack in furthering its scientific work. Some of the best surgical papers I have ever listened to were contributed by him. He was notably a fine demonstrator of material, and I often delighted to compare his work in this assembly and in the Academy of Medicine with that of Adolph Barkan as I heard it in the German Medical Society. These two men presented their cases or theses excellently.

It is well that we should have these portraits of those who have gone before into the secret house of death, and it is to be hoped that in time we may have a dwelling of our own where they may be permanently hung. Such a habitation, with its stories of the past, is of inestimable benefit to the profession in developing a medical tradition and solidarity. With this solid background, a good organization and the will to do this Society may look forward to a bright future full of beneficent endeavor.

The portrait of Harry M. Sherman possesses a peculiar value to those who knew him, in that it truly depicts his character. It shows the open, straightforward countenance, with head held erect on a good neck, based on fine, square shoulders. No man I ever knew showed so clearly in his countenance the inner workings of his mind. There was nothing to hide, for he was the personification of frankness.

In speaking of his appearance an interesting incident occurs to me. Soon after his demise Leo Newmark, one of his sincerest admirers, sent me a photograph of the bust of Marcus Aurelius, the great, stoic emperor of Rome, inquiring if I did not find a certain resemblance between it and Anax Andron, and indeed, especially in the upper part of the face, both in features and expression, the likeness is striking. Anax Andron, or King of Men, was a name given to Sherman by Newmark, partly as indicative of his grand manner, and, more especially, to convey the sincere regard he had for his character and attainments, and for his integrity, which was carried to the length of being almost a peculiarity; and for the iron rule he maintained over himself. In this self-rule and in his determination to carry through any project he had undertaken he resembled his distinguished contemporary, the late Levi C. Lane.

It was a cruious fate that accompanied both these men, that the work that they most ardently wished to accomplish should be partly marred by associates who seemed absolutely incapable of appreciating their endeavors and purposes.

As an instance of the masterful way he had of managing himself, take his attitude during the war.

At a time of life when most men seek their ease and routine work becomes a drudgery, he devoted a large share of his time to the examination of recruits, and when he was given a commission he even gladly took it as being his duty, although it meant the closure of his office. His associate was also away in the Army, and he was fully aware of the serious effect any continuous absence would have on his affairs.

He accomplished a fine day's work for this Society, for the profession in general, and for himself. I say for himself, but in no selfish way, for he was one of those who entwined his general culture, with which he was well endowed, with his medical work, so as to embellish it and to make it a real part of his intellectual development.

We are here tonight to honor Harry M. Sherman, but honor is an external adjunct and pertains rather to the honoror than to the person honored. We can not do anything to change Harry M. Sherman, he has gone beyond the boundaries of time and space, but by honoring him a change is wrought in ourselves, and by a contemplation of what he was, both in excellencies of character and in the purpose and accomplishment of his work, we clarify our own souls and stimulate ourselves to follow his example. Truly death has no dominion over such a life.

Diathermy in Ophthalmology—In discussing this subject at the meeting of August 22 Kaspar Pischel stated: "While in the usual hot application the heat is applied to the surface only, in diathermy the heat is created in the tissues itself by alternating high frequency electric current. The temperature in the vitreous can be raised to 40.7 C. — 105.3 F. — without injury, thus creating a marked hyperaemia inside the globe, as proved by the albumen contents of the aqueous." Using Dr. Koeppe's book on "Diathermy of the Eye" as a guide, Dr. Pischel discussed the indications for its use and advised to try this new therapeutic measure. Many other valuable papers were presented to the Society during August and September, but abstracts have not been furnished the Journal.

St. Joseph's Hospital (San Francisco) Staff Meeting—At the August meeting of St Joseph's Hospital staff, L. Crow gave an interesting illustrated talk on "Early X-ray Signs in Medical and Surgical Chests." Dr. L. Crow is now in charge of the Roentgenological Department of St. Joseph's Hospital and brings to it his experience in a similar capacity at the San Francisco and Southern Pacific Hospitals. With two sisters as his technicians the department has been made attractive and efficient. A. S. Musante, president of the staff, reported upon the success of the first class in the School of Nursing, and the usefulness of the "In" and "Out" register. Progress in the program for the construction of the second concrete unit of the hospital was made. New patients for July were 175 (surgical 111, medical 34, obstetrical 15, and X-ray and laboratory 14); deaths 9, and discharged 161 (recovered 115, improved 32, unimproved 5). Case records were discussed by P. Collischon, cerebral hemiplegia; R. H. Berndt, prostatic hypertrophy, and Walter Smith, eclampsia.

SAN JOAQUIN COUNTY

San Joaquin County Medical Society (reported by Dewey R. Powell, secretary)—The regular meeting of the San Joaquin County Medical Society was held at the Receiving Department of the State Hospital on the evening of September 8. Those present were: H. Smythe, B. J. Powell, C. D. Hollinger, J. D. Dameron, Grace McCoskey, L. Dozier, J. E. Barnes, A. H. McLeish, J. Hull, C. R. Harry, W. Freidberger, C. F. English, D. R. Powell with L. R. Taussig and Alfred Spalding of San Francisco as guests and speakers of the evening.

The secretary announced with deep regret the death of Dr. H. N. Cross on August 18, 1922, a member of the Society and stated that a floral piece and message of condolence had been sent to the surviving widow.

Alfred Spalding of Stanford University spoke on "Vesico-Vaginal Fistulae." Spalding illustrated his remarks with lantern slide pictures which showed very conclusively the anatomical relations and the problems which have to be solved in correcting such fistulae. He emphasized the importance of dissecting out thick layers of fascia and overlapping the same in order to get a firm support. The paper was discussed by Doctors Dameron, Harry,

English and others and Spalding answered several questions in his usual clear, concise manner.

L. R. Taussig of the University of California staff spoke on the subject of "The Radium Treatment of Carcinoma of the Lip." He was quite convinced of the advantages of the use of radium in the early stages of carcinoma on account of less scarring and the avoidance of surgical procedure. On the other hand, the discomfort of the treatment was a disadvantage and the inability to obtain a specimen for exact pathological diagnosis. Taussig showed several lantern slides of both early and advanced cases of carcinoma and stated again that the benefit of radium could only be expected in the early cases. The paper was discussed by several members present who concurred in the desirability of giving radium a chance in the early stages of carcinoma.

Buchanan Sanitarium, Lodi—It is reported that a new six-room maternity department is just being completed for this institution. The hospital contains twenty rooms for patients. The hospital is a private institution operated by R. A. Buchanan of Lodi.

SAN LUIS OBISPO COUNTY

Harrison Neal, M. D., died in March at San Miguel, California, at the age of 87. Dr. Neal was a graduate of Jefferson Medical College and spent many years in practice at Paso Robles.

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by P. C. Means, secretary pro tem)—The Society held its August meeting at the Cottage Hospital, President W. J. Mellinger presiding. S. E. Sansum read a "Preliminary Report on Insulin." After reviewing the diet in diabetes he gave a short history of the initial work in the diagnostic and therapeutic value of insulin in diabetes by J. R. MacLeod. Sansum presented the histories and charts of nine cases in which he had used this new pancreatic extract with encouraging results. G. W. Jean presented cases of cataract and sac operations. This was the largest meeting of the year, with three-fifths of the membership present. The secretary, A. C. Soper, was absent at the M. R. C. training camp at Monterey.

County Hospital—The annual report of Mr. C. G. Vandever, superintendent of this hospital, has been submitted. The cost of operating the hospital for the year was $78,914.12 or $2.40 per "patient day." Patients were divided as medical, 276; surgical, 170; tubercular, 78; contagious, 26; maternity, 29; births, 22; emergency, 3; custodial, 16. The hospital has grown from 216 admissions in 1917 to 620 in 1922.

SONOMA COUNTY

Hospitals, Clinics and Laboratories (reported by N. Juell, secretary)—Sonoma County Hospital, sixty beds, located at Santa Rosa; matron, Miss Schwab; County physician, F. O. Pryor.

Mary Jesse Hospital, twenty beds, located at Santa Rosa; matron, Mrs. Williamson.

Santa Rosa General Hospital, twenty-eight beds; Miss Levy, superintendent; H. G. Guttermuth, owner and manager.

Dr. Fisher's Sanitarium, located at Santa Rosa, seven beds; C. E. Fisher, owner and manager.

Ovalcrest Convalescent Home at Santa Rosa, Major Brandon, owner and manager.

Beaucourt Convalescent Home at Santa Rosa; C. H. Stevens, owner and manager.

Santa Rosa also has three Maternity Homes owned and operated by Mrs. Nelligan, Mrs. Manion and Mrs. Shaafsma, respectively.

Santa Rosa Clinical Laboratory, owned and operated by A. B. Hewitt.

Santa Rosa X-ray Laboratory, including radium and electrical therapeutics, owned and managed by O. N. Young.

Santa Rosa Sanitarium, thirty beds; owned and managed by C. B. Schoenfeld.

Cloverdale General Hospital, ten beds; owned and managed by W. C. Shipley.

Healdsburg General Hospital, twelve beds; owned and managed by Mrs. Marcella Jones.

Petaluma General Hospital, eighteen beds; owned and managed by Doctors Peoples and Lunsden.

Petaluma Hillside Hospital, fourteen beds; owned and managed by Mr. Carl Haderman.

Cherry Hill Hospital, Petaluma, eight beds; owned and managed by Mrs. J. F. Jones.

Burke's Sanitarium, Burke postoffice; owned and managed by Dr. Burke.

Baby Clinics—Santa Rosa, Petaluma, Sebastopol and Sonoma. These clinics are operated by the Children's Welfare Society and the Red Cross.

Dental Clinics at Santa Rosa, Petaluma, Sebastopol and Sonoma. These clinics are operated by the Sonoma County Public Health Association.

Community Clinic at Santa Rosa. This clinic meets twice a month and is conducted by F. O. Butler and Mr. Ordahl, psychologist of the Sonoma State Home.

Sonoma State Home, Eldridge, Sonoma County. F. O. Butler, medical director.

Sonoma State Home—M. Covey, formerly of Philadelphia, has been appointed assistant director to F. O. Butler, medical director of the Sonoma State Home at Eldridge.

Lafayette L. Wilson, president of the Sonoma County Medical Society, died August 16 at his home in Sebastopol.

TULARE COUNTY

Tulare County Health Center—A published report of the activities of this free health Center shows that during the past month 136 patients were cared for from ten towns in the county. The physicians of Tulare County rendered the medical service.

Hospital Project for Dinuba—Doctors Paul R. Walters, Edgar Brigham, V. B. Gregory, A. N. Loper, and Louis Seligman are reported to be behind the project to secure a new hospital of from fifteen to twenty beds for Dinuba.

Board of Medical Examiners News—The Board of Medical Examiners announces that the results of the written examination held in San Francisco in June, show that eighty-five, including graduates of the College of Osteopathic Physicians and Surgeons of Los Angeles, passed the physicians and surgeons' examination. The highest mark (93 per cent) was made by Randolph G. Flood, a graduate of Stanford Medical School, 1922.

The University of California Medical School sent forty-two graduates for examination without a single failure, a record that has been maintained for over ten years.

Twelve graduates of Chiropractic colleges passed the Drugless Practitioner written examination. Mary J. Murphy, D. C., a graduate of the Western College of Chiropractic, San Francisco, made the highest grade (85 per cent), of the Chiropractic graduates.

During 1922, graduates of Chiropractic schools have successfully passed the written examination as follows: California Chiropractic College, 2; San Francisco, 2; Kinetic College of Chiropractic, Los Angeles, 3; Los Angeles Chiropractic College, 4; Pacific College of Chiropractic, Portland, Ore., 1; Western College of Chiropractic, San Francisco, 11.

Electronic Reactions of Abrams—Those who may be interested in this apparently profitable commercial enterprise will find interesting reading in the Boston Medical and Surgical Journal, August 17, 1922, pages 268 to 270.

28	*No. 28. Anti-Vivisection Anti-Health Initiative* A destructive measure that would increase tuberculosis among the children of California, stop the production of certified milk; ruin the canning industry, expose to fatal food poisons people who use California canned and other foods; jeopardize the poultry, dairy, livestock and agricultural interests; invite epidemics, plagues, quarantine and commercial disaster; shackle scientific practice and progress; prevent effective work of health boards, veterinarians, bacteriologists, research workers; *debar forever* educated physicians and surgeons who dare to render life-saving scientific service to the people of this State, and penalize the scientific study, prevention, cure and control of diseases that attack man and animals. Vote "NO."	Yes	
		No	X

Not that We Love Animals Less, But that We Love Humanity More

The people of California defeated the destructive anti-vivisection measure two years ago by a majority of 254,000, not that we love animals less, but that we love humanity more.

This absurd Anti-vivisection act would injure animals as much as man. It would doom animals to ravaging plagues and prevent their real friends from using scientific means to save them.

It prohibits the effective scientific methods by which hog cholera, anthrax, scab, blackleg, chicken cholera, Texas fever and various animal diseases are discovered, prevented and cured.

It prohibits the manufacture of serums and vaccines for the treatment and prevention of diphtheria, smallpox, hydrophobia and lockjaw.

The preventive and curative work of physicians, the safety of surgery, the conquest of cancer, the prevention and cure of tuberculosis, syphilis, influenza, infantile paralysis and many other diseases are dependent upon ("vivisection") animal experimentation.

Ninety-five per cent of animal experiments are to determine purity and safety of drugs used by physicians, dentists and veterinarians for the benefit of man and animals.

Present laws of California adequately protect animals and prohibit inhumane treatment. There is no cruelty to animals in the laboratories of California. The scientific workers are devoted to advancing the welfare of men and animals.

The laboratories are open. The minds of the anti-vivisectionists are closed. They would substitute silly sentiment for beneficent scientific methods.

Combined with the chiropractic and osteopathic anti-health initiatives they form "THE OBTUSE TRIANGLE" which would permit the unqualified to practice unscientifically and prohibit the qualified from practicing scientifically.

The inhumane anti-vivisection measure would *debar from practice forever* physicians and surgeons who use a few guinea-pigs to save the lives of many people. Anti-vivisectionists forget that people "are of more value than many sparrows."

The truest lovers of animals recognize the need and value of animal experimentation. Ernest Harold Baynes, of whom President Roosevelt said, "He has the highest reputation in all forms of work for the care of animal life," presents and answers the vivisection question this way: "The whole question is one of proportion. If you could see two hundred and fifty mothers lined up with their babies in their arms, would you condemn them to painful death . . . in order to save from less painful death an equal number of guinea-pigs, rabbits and billy goats—or even dogs, much as we love them? Of course you wouldn't—nor would anyone who has imagination enough—to think straight and to see things in their proper proportions. . . . . It is safe to say that for every animal used in experiments a hundred human lives were saved in the World War alone."

Those who vote for this anti-vivisection measure must place a higher value upon one timid rabbit than upon a hundred brave men.

Who will vote to spread tuberculosis among the children of California? Tuberculosis is spread to children by milk and dairy products from tuberculous cattle. The control and eradication of tuberculosis among cattle would be prohibited by this anti-vivisection measure. Animal experimentation is indispensable to insure safe milk and pure food. Anti-vivisection would injure the people, animals and resources of every community of California without benefiting anybody or anything. Vote "NO" on Anti-Health Initiatives Nos. 16, 20, 28.

THE SOUTHERN CALIFORNIA MEDICAL SOCIETY

(Reported by William Duffield, President)

From a little leather-bound book, in a very clear and elegant penmanship, may be found the following: "At a meeting of the Los Angeles County Medical Society, April 6, 1888, W. G. Cochran offered the following resolution which was adopted: 'Resolved, That a committee of three be appointed to communicate with the regular physicians of Southern California to ascertain their wishes in regard to the organization of a District Medical Society.' In accordance with the resolution the president, G. W. Lasher, appointed as such committee W. G. Cochran, H. G. Brainerd and John L. Davis. The committee met and prepared a circular, explaining the purpose of the resolution; this circular together with an addressed postal card for response was then, on April 14, 1888, sent by the committee to about two hundred and fifty physicians of Southern California, including the counties of Kern, Los Angeles, San Bernardino, San Diego, San Luis Obispo, Santa Barbara and Ventura. In response to the circular about eighty replies were received, all, with two or three exceptions, favoring the proposed organization. On May 4, 1888, the committee made its report to the Los Angeles County Medical Society. Its action was approved and the committee was continued and authorized to call a meeting for the purpose of organizing a **District Medical Society.** The committee thereupon issued the call for Los Angeles, June 8, 1888. The meeting took place in Hotel Hollenbeck of Los Angeles on June 8, 1888, and about eighty physicians were present during the day."

And this is the story of the beginning of the Southern California Medical Society. Most of those who comprised that first eighty are no longer with us. But their good lives. **The District Medical Society** has brought a fellowship, a unity of effort for the good of the people and for the profession, a neighborliness, which could not be brought about by the County Society nor by the State Society in this great big empire of a State. It has never encroached upon the domain of either of its relatives, but has always brought the whole family into a better relationship twice a year.

This society has a fine record for clean, honest, scientific service, as well as for the fellowship, too. When one reads the pages of its history, one sees that these old fellows who founded it, and who were part of its earlier history, have very good reason for watching the service of those who have succeeded them. Indeed, they are very jealous of that past, and they are going to keep a sharp eye on the present of the society.

It would be interesting for the Journal to give some of the early history as one will find it in these carefully penned pages, for we know there are many members of our big State family who reach back to those days in sacred memories. There is a fine sentiment in it aside from the history—and what is there in life that is worth while that hasn't a lot of sentiment for seasoning.

Well, anyway, the next semi-annual meeting of the Southern California Medical Society—the "District Society"—will be held in Los Angeles on Friday and Saturday, November 3 and 4. Dr. Egerton Crispin, the secretary, has prepared a very excellent program—one good enough for any society, anywhere. Among the visiting speakers will be Louis Wilson, of the National Board of Medical Examiners and Dean of the Graduate School of the University of Minnesota, who will talk on the needs of the medical profession in their relation to the public, and the problems in medical education in their relation to the university and the public; E. C. Rosenow, Professor of Bacteriology in the Graduate School of the University of Minnesota, and Mayo Foundation, will present new research work in bacteriology and experimental medicine; Walter Alvarez of San Francisco will give "The Results of Clinical Observations and Blood Pressure Studies in Sixteen Thousand High School and University Students." A large number of other excellent papers by men of the "District," from Santa Barbara to Tia Juana and Mexicala.

In this society the discussions are given equal prominence with the papers, and the members who have accepted places on the program for discussion have been put in touch with the original paper, and have had much time in which to prepare their presentations. Special clinics will be held at many of the hospitals on the forenoon of the first day of the meeting. I regret my inability to furnish the Journal with the complete program, but that seems impossible at this writing. However, everybody may be assured that the two days will be crowded with excellent features from start to finish—days which will be most profitable to those who attend.

And all regular physicians are cordially invited.

BOOKS RECEIVED

The Practice of Medicine. By A. A. Stevens, M. D., Professor of Applied Therapeutics in the University of Pennsylvania; Professor of Therapeutics and Clinical Medicine in the Woman's Medical College of Pennsylvania. Octavo of 1106 pages. Philadelphia and London: W. B. Saunders Company. 1922. Cloth, $7.50 net.

Radium Therapy. By Frank Edward Simpson, A. B., M. D., Professor of Dermatology, Chicago Policlinic. 391 pages with 166 original engravings. St. Louis: C. V. Mosby Company. 1922. Price, $7.

The Healthy Child From Two to Seven. A handbook for parents, nurses and workers for child welfare. By Francis Hamilton Maccarthy, M. D. 235 pages. New York: The Macmillan Company. 1922.

A Textbook of Clinical Periodontia. A study of the causes and pathology of periodontal disease and a consideration of its treatment. By Paul R. Stillman, D. D. S., and John Oppie McCall, A. B., D. D. S. 240 pages. New York: The Macmillan Company. 1922.

The Law of Vital Transfusion and the Phenomenon of Consciousness. An account of the necessity for and probable origin of the development of sex and of the development of the conscious state in the evolution of the organic world, with a preliminary statement of fundamental cosmical principles. By Charles J. Reed. San Francisco: Occidental Publishing Company. 1921.

Hay Fever and Asthma. Care, prevention and treatment. By William Scheppergrell, A. M., M. D. 274 pages. Illustrated with 107 engravings and one colored plate. Philadelphia and New York: Lea and Febiger. 1922. Price, $2.75.

Nutrition and Specific Therapy. By Dorothy E. Lane, S. B. 185 pages. New York: The Macmillan Company. 1922.

Readings in Evolution, Genetics and Eugenics. By Horatio Hackett Newman, Professor of Zoology in the University of Chicago. 512 pages. Chicago: University of Chicago Press. 1921.

Paracelsus. His personality and influence as physician, chemist and reformer. By John Maxson Stillman, Professor of Chemistry Emeritus, Stanford University. Chicago and London: The Open Court Publishing Company. 1920. Price, $2.

The Life of Jacob Henle. By Victor Robinson, M. D. 117 pages. New York: Medical Life Company. 1921.

The Eighteenth Amendment. And the part played by organized medicine. By Charles Taber Stout. 216 pages. New York: Mitchell Kennerley. 1921.

American Red Cross Work Among the French People. By Fisher Ames, Jr. 178 pages. New York: The Macmillan Company. 1921.

Physical Diagnosis. By W. D. Rose, M. D., Lecturer on Physical Diagnosis and Associate Professor of Medicine in the University of Arkansas. Second edition. 736 pages. 309 illustrations. St. Louis: C. V. Mosby Company. 1921. Price, $8.50.

History and Bibliography of Anatomic Illustration in its relation to anatomic science and the graphic arts. By Ludwig Choulant. Translated and edited by Mortimer Frank, B. S., M. D. 435 pages. Chicago: University of Chicago Press. 1920.

Smithsonian Institute Bureau of American Ethnology, Bulletin 73; Early History of the Creek Indians and Their Neighbors. By John R. Swanton, Washington, Government Printing Office 1922.

Same, Bulletin 75; Northern Ute Music. By Frances Densmore, Washington, Government Printing Office, 1922.

A Text Book of Gynecology. By James Young, D. S. O., M. D., F. R. C. S. (Edin.), Assistant Physician, Royal Maternity Hospital; Lecturer in Clinical Gynecology and Clinical Obstetrics, Edinburgh University; late University Clinical Tutor in Surgery; Gynecologist, Provident Dispensary, Edinburgh; Examiner, Central Midwives Board of Scotland, etc. 183 Illustrations. New York: The Macmillan Company. London: A. & C. Black, Limited.

Endocrine Glands and the Sympathetic System. By P. Lereboullet, P. Harvier, H. Carrion, A. G. Guillaume. Translated by F. Raoul Mason, M. D., Instructor in Pediatrics, New York Post-Graduate Medical School and Hospital; Assistant Attending Physician, Willard Parker Hospital; Assistant Pediatrist, New York Post-Graduate Medical School and Hospital, Out-Patient Department; Assistant Attending Physician, Babies' Ward, New York Post-Graduate Medical School and Hospital. With the collaboration of Daniel R. Ayres, A. B., M. D., Assistant Professor of Gynecology, New York Post-Graduate Medical School and Hospital; Assistant Visiting Obstetrician, City Hospital, New York. Philadelphia and London: J. B. Lippincott Company. 1922.

Diseases of the Thyroid Gland. By Arthur E. Hertzler, M. D., F. A. C. S., Professor of Surgery in the University of Kansas School of Medicine; Surgeon to the Halstead Hospital, Halstead, Kansas; Surgeon to St. Luke's Hospital and St. Mary's Hospital, Kansas City, Mo., and to Provident Hospital, Kansas City, Kansas. With a chapter on Hospital Management of Goiter Patients, by Victor E. Chesky, A. B., M. D., Associate Surgeon to Halstead Hospital. 106 original illustrations. St. Louis: C. V. Mosby Company. 1922.

Obstetrical Nursing. A Text Book on the Nursing Care of the Expectant Mother, the Woman in Labor, the Young Mother and Her Baby. By Carolyn Conant Van Blarcom, R. N., formerly Assistant Superintendent and Instructor in Obstetrical Nursing and the Care of Infants and Children at the Johns Hopkins Hospital Training School for Nurses; Author of "The Midwife in England." With 200 illustrations and 8 charts. New York: The Macmillan Company. 1922.

Food, Health and Growth. By L. Emmett Holt, M. D., LL. D., President Child Health Organization; formerly Professor of Diseases of Children in the College of Physicians and Surgeons, Columbia University, New York. A discussion of the nutrition of children. New York: The MacMillan Company. 1922.

X-Ray Dosage in Treatment and Radiography. By William D. Witherbee, M. D., Radiotherapist, Presbyterian Hospital, New York; formerly Roentgenologist, Rockefeller Institute, and John Remer, M. D., Radiotherapist, New York Hospital, New York; Consulting Radiotherapist, United Hospital, Port Chester. New York: The MacMillan Company. 1922.

Surgical and Mechanical Treatment of Peripheral Nerves. By Byron Stookey, M. D., Associate in Neurology, Columbia University; Assistant Professor of Neurosurgery, New York Post-Gradate Medical School and Hospital. With a chapter on Nerve Degeneration and Regeneration by G. Carl Huber, M. D., Professor of Anatomy, University of Michigan. Octavo volume of 475 pages with 217 illustrations, 8 in color and 20 charts. Philadelphia and London: W. B. Saunders Company. 1922. Cloth, $10 net.

Obstetrics for Nurses. By Joseph B. De Lee, M. D, Professor of Obstetrics in the Northwestern University Medical School, Chicago. New (sixth) edition, entirely reset. 12mo of 525 pages, with 245 illustrations. Philadelphia and London: W. B. Saunders Company, 1922. Cloth, $3 net.

Diseases of the Skin. By Henry H. Hazen, A. B., M. D., Professor of Dermatology in the Medical Department of Georgetown University; Professor of Dermatology in the Medical Department of Howard University; sometimes Assistant in Dermatology in the Johns Hopkins University. Second edition, 241 illustrations. St. Louis: C. V. Mosby Company, 1922.

BOOK REVIEWS

Management of the Sick Infant. By Langley Porter and William E. Carter. St. Louis: C. V. Mosby Company. 1922.

The proper construction of a textbook or of any book of reference should be based directly on the needs of the people who are expected to use it. The neglect of this point of view is responsible for the small value of many—perhaps most—of the numerous texts which are turned out every year. The majority of them are written by teachers and addressed to their students and bear the mark of the class-room rather than of actual life and reality. Medical books especially suffer from this fault. Too few of them are put out by the clinician for the clinician. Too few of them readily yield the answer to the questions for which the practitioner turns to their pages. He may wish to know to what diagnosis a particular set of unusual symptoms point, or what is a better treatment than his own for a given disease, or the details of a therapeutic technique with which he is familiar with only in principle. In the first case, consulting the average book he will find that he must read over the descriptions of several diseases in the same general group; in the second case, he is apt to find the customary "standard" methods with which he is already familiar, and in the third case, he will rarely find any help at all. It is a frequent comment that textbooks serve to perpetuate the mistakes of their predecessors. Certainly most of them are not based entirely or even in large part on the direct experience of their authors. Because it was an exception to this rule, Osler's "Practice of Medicine" took the medical world by storm with its freshness and its originality of observation, while maintaining a critical appreciation of the old.

It is to the credit of the Pacific Coast that its most recent—and one of its few—medical texts should bear the same stamp of reality and should be so intelligently planned to meet actual needs. It can be at once recommended to any practitioner

[redacted]

tics, is unique in textbooks in English, and, indeed, is not equalled for completeness in any language. There is no reason why the general practitioner, acquainted with the principles of medical technique, should not be able from a careful perusal of this book to carry out the methods which hitherto have been left to a few specialists. Further, his nurse by referring to the book herself will be able to have all the necessary equipment prepared for him in advance—a considerable saving of time.

The reviewer has for a number of years considered that there were only two American texts which were indispensable to the practicing pediatrist—that of Holt and Howland, and that of Morse and Talbot. To these he is now inclined to add that of Porter and Carter because of its practical utility and its freshness of matter and because it offers material which is not to be found elsewhere in readily available form. H. K. F.

Principles of Immunology. By Howard T. Karsner, M. D., and Enrique E. Ecker, Ph. D. 309 pages. Illustrated. Philadelphia and London: J. B. Lippincott Company. 1921.

This is a valuable guide for students or practitioners of medicine who desire a concise statement of the facts and the hypotheses concerning resistance to infection. The general arrangement of the text is excellent and the difficult subject is presented in a remarkably clear manner. Facts established by experimental studies are detailed and supplemented by brief discussions of the practical and theoretical bearing of the phenomena upon disease and resistance in man. In twelve chapters the following subjects are reviewed: Virulence of organisms, general conditions of infection and resistance, general phenomena of immunity, toxins and antitoxins, agglutinins and precipitins, cytolysins, cellular resistance, complement fixation, application of complement fixation to the diagnosis of disease, hypersusceptibility, hypersusceptibility in man and defensive ferments. The practical application of immunology to the prevention and cure of disease has been summarized in three appendices, dealing with the therapeutic employment of blood serums, prophylactic vaccination and vaccine therapy. Throughout the text valuable information is given relative to the technical execution of experiments. Some of the customary laboratory procedures are explained and enhanced by drawings or colored plates. This book is a valuable addition to any medical library. K. F. M.

Clinical Diagnosis. A textbook of clinical microscopy and clinical chemistry for medical students, laboratory workers and practitioners of medicine. By Charles Phillips Emerson, A. B., M. D. 5th ed. 726 pages. Illustrated Philadelphia and London: J. B. Lippincott Company. 1921.

It is ten years since the last edition of this book appeared. In its preface, the author condemns the present separation of laboratory and ward, and "No matter how successful a man may be, he has no right to entrust his laboratory work entirely to others. . . . . The one who takes the history of the patient and makes the physical examination is the only one who can interpret correctly a laboratory finding." Herein lies the value of this book, one of the best on clinical diagnosis.

L. E.

The Surgical Treatment of Non-Malignant Affections of the Stomach. By Charles Greene Cumston, M. D., and Georges Patry, M. D. 349 pages. Philadelphia: J. B. Lippincott Company. 1921.

There is nothing new in this book, but it is a compilation founded on a wide study of the literature and personal visits of the authors to a great many foreign clinics. L. E.

Tuberculosis in Infancy and Childhood. By J. Claxton Gittings and Frank Crozer Knowles and Astley P. C. Ashhurst. 273 pages. Illustrated. Philadelphia and London: J. B. Lippincott Company. 1922.

This book is a most concise, though at the same time complete, presentation of tuberculosis in infants and children. In slightly over 250 pages, the authors present a short historical review, general aspects of the disease and detailed description of the disease in the several organs; also instructions for the application of various tests.

To tuberculosis of the skin (F. C. Knowles) is given a very interesting and extensive chapter, whereas bones and joints have been treated rather too briefly. The notes on treatment of tuberculosis

are in general sane and practical. However, advice somewhat exceeds the margin of safety in openly advocating "euthanasia by toys" in certain cases.
M. H. L.

The Place of Version in Obstetrics—By Irving W. Potter, M. D., F. A. C. S. 138 pages, with 42 illustrations. St. Louis: C. V. Mosby Company, 1922. Price, $5.

Unfortunately, only about fifty pages of the one hundred and forty of this monograph contain personal experiences of the author. Some seventy pages are devoted to the history of version. This portion of the volume is unquestionably the more interesting one, since it quotes many of the classical authorities verbally. As far as the chapters on technique are concerned, there is nothing new that has not been done in most every well conducted maternity. There is little argument offered and less proof given that the author's contention of delivering all women by version and extraction can be accepted for general teaching. Like in all other fields where technical skill can be developed to the finest point by a large amount of experience, so in obstetrics Potter has shown that this can be done without undue risk to the patient and the child. It is interesting that his percentage of Caesarean Sections runs close to 10 per cent of all cases delivered.

In a monograph like this one would expect the author to give his complete experience with this work rather than just a very meager discussion of the work of two years.

When reading the last chapters one can not help but feel that the author was hurrying to finish his volume for the press. I refrain from discussing the style of presenting the subject.

There are many salient points made in this book that are worth while to scrutinize. Aside from that and the historical introduction, this monograph is decidedly unsafe in the hands of students and beginners. L. A. E.

Clinical Electrocardiography—By Frederick A. Willius, B. S., M. D., M. S., in medicine. One hundred and eighty-eight pages, with 185 illustrations. Philadelphia and London: W. B. Saunders Company, 1922.

The author shows that he appreciates the difficulties of the study. He has carefully digested the literature on the subject and gives it to the students of electrocardiography in an easy, digestible form. In his numerous pictures of electrocardiograms in cases of angina pectoris, it would have been better had he called attention to the peculiar characteristics, if any were present, in each of the electrocardiograms which he shows. H. S.

An Essay on the Physiology of Mind. An interpretation based on biological, morphological, physical and chemical considerations. By Francis X. Dercum. Philadelphia and London: W. B. Saunders Company, 1922.

This 150-page essay of Dercum's is a protest against the attitude of those metaphysicians and psychologists by whom "the phenomena of mind have been approached as though they were peculiar in their character and being; as though a difference, essential and intrinsic, separated these phenomena by a wide and hopeless gap from all other phenomena of nature." In the first part of the book, one begins with the unicellular organism without nervous system, proceeds by way of the sponges through the fishes and the higher vertebrates to the fully developed human. No especial difficulty is encountered until one meets the word "consciousness" on page 82. The rest of the book is devoted to bridging the gap. The final chapter endeavors to explain the psychoses and the psycho-neuroses in terms of physiology. It is good reading for those who have read much or who will read much. Others may as well let it alone. E. W. T.

BUSINESS AND THE BUSY PHYSICIAN

Why not let our advertisers help you?

Drugs and Chemicals—The teachings of the physiological action of drugs and chemicals are based primarily upon the quality of the chemical. A certain element of success in the treatment of diseases, therefore, depends upon the quality of the prescribed agents. In many instances not enough attention is given to this important feature of medicine. Physicians have come to rely for accuracy in the manufacture of chemicals upon the integrity of the manufacturer and also upon the reports of the Council on Pharmacy and Chemistry of the A. M. A.

It is not the policy of the Journal to commend one good manufacturer above another, but we will not knowingly carry the advertisement of any manufacturer or distributing agent who has not the endorsement of the laboratories of our own national association. The advertising columns of this issue of the Journal carry manufacturers' announcements of a number of chemicals and drugs. These have all been accepted by the Council on Pharmacy and Chemistry. In this list may be mentioned the medicated alcohol of the Mifflin Chemical Corporation for external use; "Cinchophen" of the Abbot Laboratories; anti-toxins, serums and vaccines of Parke, Davis & Co.; the Cutter Laboratories; Eli Lilly & Co.

More general manufacturers and distributors of standard drugs and chemicals who hold accredited standing on the advertising pages of this Journal are: Lederle Anti-toxin Laboratories; Powers-Weightman-Rosengarten Company; The Wander Company; The Wilson Laboratories; E. R. Squibb & Sons.; Hynson, Westcott & Dunning; Schering & Glatz; Arlington Chemical Company; Maltbie Chemical Company; Laboratories of G. H. Sherman, M. D.

The drugs and chemicals of these manufacturers may be commended so long as their advertisements are accepted by this Journal.

More About Investments—The attention of all of our readers is called to the advertisement of E. H. Rollins & Sons in the advertising columns of this issue of the Journal. This is one of the oldest and most reliable of the security and investment houses of this country. In addition to careful scrutiny of securities, the representatives of this house offer personal service to physicians in selecting securities and investments.

It is pleasing to note that physicians are utilizing more and more legitimate channels of investment for their earnings than we did as a class in former years. Financial agents assure us that it is constantly growing more difficult to sell physicians the proverbial "wildcat" stocks and investments, although as a class we are still toward the top of the list of gullibles.

Physicians interested in investments and securities will make no mistake in consulting E. H. Rollins & Sons before they act—not afterwards, as we often do.

We believe that every physician who holds a government, state or county position should be a member of the State medical organization, and the failure of any acceptable physician to be a member is certainly a sign that he is not awake to his own best interests. Organized medicine stands for the advancement and protection of its members and the protection of the public against incompetent and unscrupulous practitioners; so if you are competent and ethical you should get aboard, and when you get aboard don't rock the boat.—Nevada Medical Bulletin, August 15, 1922.

EXTENSION WORK

The following additions have been made to the Extension Lecture courses offered by members of the State Society to local societies. (See November, February, March, June, and July Journals for other lectures.)

G. Carl H. McPheeters,
1021 Mattie Bldg., Fresno.

I—Obstetrics vs. Midwifery.
1. A brief historic account of the oldest branch of medicine.
2. The evils of the midwife system briefly set forth.
3. The beginning and rise of the present-day obstetrics.
   (a) Instruments in Obstetrics.
   (b) Anasthesia in Obstetrics.
   (c) Surgery in Obstetrics.
   (d) Prenatal care in Obstetrics.
   (e) Postpartum care and follow-up.
4. Development of Obstetrics.
5. Present status of Obstetrics as a branch of medicine. Most often combined with Gynecology, sometimes with Pediatrics and occasionally practiced by itself alone.
6. The great need of better Obstetrics as shown by maternal and infantile mortality and morbidity in the United States.
7. Rewards of better Obstetrics to patients and physicians set forth.

II—Prenatal Care in Obstetrics.
1. Great value of examination of both parties prior to marriage, a matter physicians should emphasize.
2. Each married woman should have a complete physical examination before each pregnancy begins and especially before her first pregnancy. Physicians must teach laity the importance of this.
3. Physical examinations before pregnancy will disclose anemia, focal infections, pelvic deformities, and gross diseases incompatible with normal pregnancies, such as tuberculosis, syphilis, diabetes, nephritis, heart disease with hyperthyroidism, whenever present. Many married women become pregnant with diseases present, of which they are not aware.
4. Examination early in pregnancy. Anemia and focal infections are exhibited by most women who present themselves for examination.
5. Written instructions given patient at her first visit. Treatments for anemia and other troubles begin at once. Care of abdomen and breasts advised. Urine examinations, visits to doctor, diet instructions, when needed.

III—Care of the Abdomen and Breasts in Pregnancy. (Illustrated with lantern slides.)
1. Striae—formation of skin.
2. Diastasis and distension of abdominal muscles.
3. Visceroptosis, which often includes ptosis of bladder and rectum.
4. Lordosis with posture disturbances; the "pot-belly" exaggerated by use of high-heel shoes.
5. Evils of modern dress brassier, worn by most women—pendulous, flat breasts and depressed nipples. Such breasts are worse after pregnancy and lactation.
6. Means of preserving figure-profile in pregnancy and lactation.
   (a) Massaging abdomen during the whole of pregnancy. Author's method described and illustrated.
   (b) Supporters for pregnant abdomen. The great mistake of going without any support. Supporters during pregnancy prevent distension of abdominal muscles with weakening of voluntary powers, and later visceroptosis because of weakened muscles.
   (c) Restoration of flat, pendulous breasts preparatory to function. Author's methods described. Maternity brassiers described and illustrated. Value of proper massage preparatory to function. Assistance of the endocrines where such assistance is clearly needed.

IV—The Toxemias of Pregnancy and their Treatments.
1. Facts causing toxemias in pregnancy.
   (a) Organic diseases, such as nephritis, tuberculosis, diabetes, syphilis, hyper-thyroid disease, active heart disease and pyelitis.
   (b) Minor foci of infection, such as pyorrhea alveolaris, nasal catarrh, nasal sinus infection, infected tonsils, lymph adenitis, cervicitis and hemorrhoidal infection.
   (c) Conditions secondary to disease: anemia, constipation, hyperacidity, headache, excessive nervousness and endocrine disturbances.
   (d) Types of toxemia described.
      1. Mild types and prognosis.
      2. Severe type and prognosis.
2. Treatments.
   (a) Treatments of mild type in detail.
   (b) Treatments of severe type in detail.
3. Prophylaxis of toxemia of pregnancy.
   (a) Pre-nuptial physical examination (every girl and young woman intending marriage should be examined).
   (b) By physical examination before pregnancy is undertaken.
   (c) By pre-natal physical examination and observation of the expectant mother.
   (d) By immediate correction of anemia, eradication of focal infections, and correction of constipation, hyperacidity and the early nausea and vomiting of pregnancy.
   (e) By immediate attention to every patient whose examination shows she is an apt subject to toxemia because of poor physical condition, or evident endocrine imbalance.
   (f) By immediate treatments for mild toxemia as a preventive of more severe toxemia.

OBITUARY

ALEXANDER RICHTER CRAIG

Dr. Alexander Richter Craig, secretary of the American Medical Association, died August 25, 1922, while on his vacation. Dr. Craig had not been well for some time, but that he was seriously ill had not occurred to him nor to his friends.

The American Medical Association, as well as its constituent State and county branches, all suffer a keen loss in the passing of Dr. Craig. His usefulness to medicine and public health and to the A. M. A. as an organization cannot be fully appreciated by those who were not in intimate contact with him in the central office.

The Medical Society of the State of California extends to Dr. Craig's bereaved family and his friends our sympathies in the hour of their bereavement.

DEATHS

McGarry, John A. Died in San Francisco, July 1, 1922, aged 47 years. Graduate L. A. Dept., University of California, 1898. Member of Los Angeles County Medical Society.

Palmer, Wilton H. Died in Los Angeles, August 24, 1922, aged 72 years. Graduate of Homeo. Hosp. Coll., Ohio, 1879.

Cooke, William Henry. Died at Redondo Beach, Calif., July 28, 1922. Graduate of Queens Univ., Ontario, Canada, 1888.

Reynolds, George P. Died at San Francisco, Calif., August 4, 1922, aged 75 years. Graduate of Medical Dept., Syracuse Univ., N. Y., 1873. He was a member of Alameda County Medical Society.

Wilson, Lafayette J. Died at San Francisco, August 15, 1922, aged 38. Graduate of Hahnemann Med. Coll. of Pacific, 1915. Member of Sonoma County Medical Society.

Nash, Francis O. Died at Hollister, Calif., August 19, 1922, aged 80 years. Dr. Nash was a graduate of Bowdoin Med. School, Maine, 1868. He was a veteran of the Civil War and had been a resident of Hollister for over 50 years. Was a member of the San Benito County Medical Society.

Bond, Frederick Taylor. Died at Vallejo, Calif., August 23, 1922, aged 58. Graduate of the Medical Dept., Univ. of California, 1890. Member of Solano County Medical Society.

ORIGINAL ARTICLES

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

The author of an article appearing in the JOURNAL *is entirely responsible for all statements and conclusions. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the language and method of presenting their subjects. All manuscripts will be carefully read, but editorial privileges will be exercised only to a very limited extent. It is believed that the manner of presentation of any subject by any author determines to no small degree the value of his conclusions. Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented by the author as little disturbed as possible by the editors. However, the right to reduce or reject any article is always reserved.*

FREUD AND THE FREUDIANS.*

By EVA CHARLOTTE REID, M. D.

There is no physician living today whose name is more widely known and frequently used by both the medical profession and the laity than that of Professor Sigmund Freud of Vienna. The various derivatives of his name, freudian, freudianism and the freudians are now used as common nouns and adjectives, and written without a capital letter, in the same manner as we speak of a ford car, an edison phonograph or a bell telephone.

Probably no theories ever propounded produced more warm adherents and more bitter antagonists than those of Freud. When such is the case one is led to suspect that the theories are a composite of truth and error and that the adherents see only the former and the opponents the latter. It has therefore been the duty of those who were more or less neutral on the subject to smelt out in the crucible of experience the truth from the error.

Hysteria as a definite entity was first described by Charcot in 1884. He demonstrated that traumatic neuroses could be produced by purely psychic causes, and produced paralysis by hypnosis and even suggestion. In his treatment he adhered strictly to mechanical and chemical therapy. Pierre Janet went a step further and cured a case of traumatic hysteria by hypnotizing the patient, taking her back to the time when the shock occurred and suggesting that it was harmless. Gower and Mitchell in England and Prince, James, White and Sidis in America produced similar results under hypnosis.

It remained for Freud to discover that the neuroses produced by psychic trauma could be cured by psycho-analysis and psychotherapy without hypnosis. In 1893 Freud and Bruer wrote an epoch-making article entitled "Psychic Mechanisms of Hysterical Phenomena" and in 1895 they gave to the world "Studies in Hysteria" which contained the fundamental ideas which led to psycho-analysis, and in 1901 "The Psychopathology of Everyday Life." These writings have revolutionized psychiatry and psychology, and bid fair to revolutionize medicine.

Little attention was paid to the writings of Freud until 1911, when a neurologist of Vienna gave a public lecture in which he condemned Freud and all his works in the most vivid terms. To prove his assertions he read extracts from the writings of Freud. The result was, of course, the opposite from what he had intended, and the audience arose en masse and migrated to the book stores to purchase the books of Freud. For months the printing presses were kept busy supplying the demand.

In America the "old guard" in neuropsychiatry, led by Dercum, Burr, Mills, Dana and others, at first ignored the Freudian movement, but as its adherents, led by White, Jeliffe, Brill and Ernest Jones, grew in numbers and literary productivity the neuropsychiatric world became more or less divided into two camps, freudians and anti-freudians. While the conflict never reached the point of open denunciation and vituperation as it did in Europe, no neuropsychiatric meeting is considered complete without a more or less heated discussion of freudianism. The freudians have insinuated that the resistance of the opposition was based on repressed complexes which might be eliminated by psycho-analysis. The anti-freudians have hinted that anyone who interprets the dreams and subconscious reactions of his patients after the manner of the freudians must himself be abnormal. Morton Prince believes they are both psychological problems as much as a case of psychoneurosis. More and more neuropsychiatrists are taking a middle ground, and are making use of the great therapeutic agent of psycho-analysis while discarding the erroneous doctrines of Freud.

To give a brief resumé of the theories of Freud is not easy. It is characteristic of Freud and the

*Read before the San Francisco County Medical Society, September 5, 1922.

freudians that nowhere do they give a clear, concise, scientific description of their methods. The fundamentals of the theory of freudian psychoanalysis might be summarized as follows:

First—The instinct of reproduction is paramount in the individual.

Second—In the infant there are certain erogenic zones scattered throughout the body, principally around the orifices. The sensations arising from these zones are sexual in nature and are present from earliest infancy. The sensations from these scattered erogenic zones are in the normal, concentrated in the reproductive organs by a process of evolution. Evolution may fail to progress normally, these zones may fail to concentrate and the individual thus retains the desire for infantile methods of satisfaction. When these desires are consciously indulged, sex perversion is the result. When they are subconscious and repressed they come forth as a neurosis which is a symbolic attempt at wish fulfillment. In other words, sex perversion represents the positive and psychoneuroses, the negative phase of the miscarriage of the sex instinct.

Third—That hysterical symptoms express symbolically ideas which lie below the level of consciousness and are always of the nature of unfulfilled unrecognized wishes.

Fourth—The repressed idea is always of a sexual nature and is usually founded in incestuous desires.

Fifth—The wish was once conscious, but on account of its painful character, has been repressed.

Sixth—That repressions are due to the ban which religion and social conventions have set upon the manifestations of the elemental instincts. In the conflict between the inherent sex instinct and artificial culture the neurosis serves as a compromise.

Freud at first used hypnosis but found that he could investigate the subconscious by means of free association and dream analysis. Later he added word association. Free association he practiced by allowing the patient to reproduce his life history. All gaps, evasions, subterfuges and contradictions were followed up by questioning. In elaborating his theories Freud coined a number of new terms which have since become popular. A *complex* is a combination of ideas of high emotional value which exists in the subconscious mind and which demands a certain outlet which produces satisfaction. If the satisfaction demanded is contrary to the ethical and moral standards of the conscious mind there results a *mental conflict*. If the conscious mind is the victor in the conflict the complex is *repressed*. The force which prevents the repressed complex from coming to the surface Freud calls the *censor*.

Dreams, according to Freud, always express a wish fulfillment. This wish is always subconscious and always of a sexual nature. These wishes, which are too repulsive to appear in their native hideousness, have to be camouflaged as symbolic representations, the censor being less active in the sleeping than the waking state allows them to appear in this form. The symbolization must be interpreted by the analyst. "Dreams are composed of threads which extend away back into the subconscious mind and each thread must be followed separately."

Word association is practiced by the selection of one hundred words. These words are given to the patient and he is told to respond with the first word that comes to his mind. A stopwatch is used to ascertain the average reaction time of the patient. A word that produces a long time reaction is noted as a *complex indicator*. The list of words is repeated and a word that produces a different response the second time is also a complex indicator. These words are then followed up one by one by free association.

When the repressed complex has been discovered there must be a *transference* of the repressed wish from the original object to the person of the analyst. It is then the duty of the analyst to effect a *sublimation* of the libido or sex instinct to useful and ethical activities.

The theory that the instinct of reproduction is paramount in the individual and that the sex instinct supplies the only dynamic force in the production of the psychoneuroses has long since been abandoned by the majority of psychiatrists. The war proved what many of us had already known, namely, that the old adage "self-preservation is the first law of nature" still holds good. In the majority of cases of psychoneuroses occurring in the army, the element of sex was entirely lacking. My personal experience which covers fifteen years and has been confined chiefly to the middle and lower classes of society, has proven to me that the causes of psychoneuroses are as varied as the patients themselves are varied, and anyone who approaches the problem with the preconceived idea that all the psychoneuroses found in sex or any one other cause will fail to interpret the symptoms of his patients correctly. I should say that less than half of the cases I have examined have anything to do with sex. First among the causes I would place maladjustment of the individual to his environment. Myerson has aptly said: "Psychoneurotics are individuals not willing to accept the odious conditions in which they find themselves and yet not strong enough to change them." In these cases the inferiority complex frequently plays a part. In the struggle to handle a job that is too big for the individual the psychoneurosis proves a graceful and apparently legitimate way out. In the case of the married woman of moderate means the fear of pregnancy usually hangs over her like the sword of Damocles. This fear not only includes the discomfort of pregnancy, the danger, suffering and expense of childbirth, but bringing into the world a child whom she cannot properly feed, clothe and educate. This conflict is especially acute in women of the Catholic faith, the tenents of which forbid all forms of birth control. The psychoneurosis provides an escape from the net in which she is entangled. If she is persistent in her indisposition and also persistent in her attendance at the

office of the surgeon, her complex may disappear via the surgical route.

The theory of infantile sexualism is ingenius but absurd. To claim that the satisfaction of securing nourishment is secondary in the infant to sex satisfaction in nursing is ridiculous. In the theory of sex perversion Freud overlooks the ductless glands, and the fact that the pervert is usually, perhaps always, one of nature's mistakes in endocrinology.

The theory that the conflict which produces a psychoneurosis is always unconscious is likewise untrue. The mechanism of the psychoneurosis is unconscious, but the conflict itself is more or less conscious. In many cases it is vaguely realized, but the patient usually because of an inherent cowardice has never analyzed his difficulty and faced the situation frankly, although conscious of its existence.

The theory that all dreams found in unfulfilled sex desires is also untrue. Nothing could be more absurd and far fetched than the dream analysis of the freudians. It is safe to say no two of them would analyze a dream exactly the same. Dreams, especially in primitive minds, are usually simple wish fulfillments and found in self rather than race preservation.

The theory that the analysis of a conflict requires weeks and months and years is a pernicious doctrine. Brill states it takes two weeks to get acquainted with the patient, and that the analysis may require two years. No good can come from keeping the mind of a patient fixed upon himself and his sex instinct for two years. Sadler says, "Man can exist at the poles or the equator, he can eat almost anything or everything but he cannot long stand self-contemplation." Prolonged analysis induces morbid introspection and retrospection. The freudian presupposes in the mind of his patient some secret perversion or sex abnormality which in the majority of cases does not exist, and all sorts of pernicious suggestion has been put into the minds of the young by the probing of these so-called psycho-analysts.

The theory of transference is fraught with much danger, especially if the analyst and the patient be of the opposite sex. Freud states that "analysis without transference leads to introversion, and transference without analysis to slavish subliminaation and mental bondage." He also states that it might be claimed that there are three ways of handling a transference, first, by a legitimate union between the patient and the analyst; second, by breaking off all relations and bringing the analysis to a close; and third, by an illegitimate temporary love relation.

He disavows the use of any of these methods. Brill admits that there may be a "moral danger to the practitioner of the art" (he does not mention the danger to the patient), and Pfeister states, "A strong reserve is necessary on the part of the analyst, otherwise the patient will cling to him." The fact that these writers admit the danger shows it is a real one, and one is led to wonder if all those who "practice the art" have the "strong reserve" of which Pfeister speaks. The whole theory of Freudian analysis depends too much upon the personality and imagination of the analyst and his ability to interpret symptoms correctly. The analyst who starts with the premises that all mental conflict found in sex will read into the mind of his patient the ideas that dominate his own. In this way it is open to artifacts of the most insidious kind.

One of the evils freudianism has brought in its train is the lay psycho-analyst. A book of five hundred pages has been written by Pfeister to teach clergymen and teachers the art of freudian psycho-analysis. He states that only those should practice the art who themselves have undergone a "psycho-analytical purification," and we have seen the spectacle of laymen who have no other qualification except the fact that they have undergone a "psycho-analytical purification" for a psycho-neurosis and who have had no fundamental training in either psychology or medicine, setting themselves up as professional psycho-analysts. Incalculable harm has been done by these lay psycho-analysts who are incapable of differentiating between an organic condition, a psychosis and a psychoneurosis. This is especially true in depression of the maniac-depressive type, notably involutional melancholia where the patient is given to morbid introspection and self-accusation.

Probably the worst inditement of freudianism is the influence it has had on the moral tone of the world at large. Its adherents have flooded the market with a literature which for pure obsenity and subtle and pernicious suggestion probably surpasses anything ever written. If the productions of Ernest Jones, Brill, Roby and others had not been written under the guise of science they would have been forbidden the use of the mails. These books have found their way into every university and public library and are being devoured by students and the laity. As a result, the moral tone of the community is lowered. As one writer says, "It has furnished a pseudo-scientific justification for allying ourselves with the brutes." What was considered virtues by our fathers are now considered repressions and inhibitions by the younger generation. They forget that it was by these virtues, or inhibitions of the elemental instincts that the human race has raised itself above the level of the animal to its present cultural and mental status. Religion which has been the most powerful factor in elevating the human race is regarded by the freudians as being founded on symbolism which has its roots in sex, and all the higher moral, social and ethical activities as manifestations of the sex instinct which have been sublimated.

Having considered the errors and resulting evils of the doctrines of freudianism, we will now consider the benefits derived from the truths contained in these doctrines. Freud has been to psychology and psychiatry what Darwin was to physiology and biology. He showed that the unconscious mind bears the imprint of hundreds of thousands of years of evolution. He preached the doctrine

of psychic determinism and showed that nothing happens by chance. He demonstrated the tremendous importance of childhood impressions and environment, and the danger of carrying over into adult life childish reactions and dependencies. He showed how to analyze the happenings of everyday life and called attention to the significance of forgetting of words and names, substitutions and evasions. Truths that were vaguely recognized for centuries were crystallized and given a name by Freud. Take, for instance, the word overcompensation. This reaction was recognized by Bulwar-Lytton in his Richelieu, when the old cardinal says, "the man bows too low," and Shakespeare when he says, "he doth protest too much." Freud showed the significance of this reaction and how to use it in analyzing patients. The patient who volunteers the information that he loves his wife devotedly gives the examiner a clue upon which to work. The theories of Freud have thrown a flood of light not only on the etiology of mental disorders, but upon the causes of domestic infelicity, social unrest, vagrancy, prostitution and crime.

The observations which led Freud to the conclusion that all repressions were of a sexual nature were the logical reactions in his patients to the viewpoint of the Victorian age, when the mention of anything pertaining to sex was considered vulgar and obscene. In the school books on physiology the pelvis is omitted and no mention is made of the process of reproduction. Naturally in the minds of the young there resulted ignorance, misunderstanding and superstition which brought about isolation, a feeling of shame, guilt and remorse. Freudianism, which has carried the present generation to the opposite extreme, may show the world the need of safe, sane and scientific sex instruction of the young.

Before the advent of freudianism the psychologist immured in his library and his laboratory was interested only in academic discussions of the component parts of the mind and their relation to each other, threshold sensations and time reactions. He had no interest in the man on the street, or the girl in the factory, or why Murphy got drunk and beat his wife or why the Jones boy left home. All that is changing and through the influence of Freudianism, psychology is becoming humanized and helpful.

The greatest service rendered by Freud is to the medical profession itself. His doctrines were given to the world at a time when the practice of medicine was rapidly becoming a matter of diagnosis and treatment by means of a huge, unwieldy, complicated machine. In the multiplicity of clinical and laboratory tests and surgical procedures the physician had forgotten the patient himself. If after every test had been applied, every organ investigated, those that were misplaced were tied down or tacked up or removed, the patient still complained, he was given a placebo or told he was suffering from imagination and advised to go home and forget about his pain. These patients furnished the wonder cures for the fifty-seven different varieties of mental healers and bloodless and drugless practitioners that sprang into being. The medical profession had not kept up with the trend of the times and failed to recognize the power of the mind over the body. The wonder is that through all the ages of faith cures and so-called miracles the medical profession had failed to grasp the great truth which Freud discovered. These cults and practitioners came into being in direct response to a call for help from a suffering people. The Church honestly and the charlatan dishonestly attempted to fill the need that the medical profession had ignored. The multiplicity and activities of these cults are now causing the profession some anxiety. The cure for the condition lies not in ridicule nor in litigation nor legislation. It lies in teaching the physician to deal with his patients more skilfully than the charlatan or the mental healer. The average physician is ten times better equipped in education and experience to deal with the mental problems of his patient than the charlatan or the mental healer, if he would only take the time and trouble to do so. The physician who has not learned to observe and note the mental reactions of his patients is liable to very serious error. I have said that no one should treat the abnormal mind without a knowledge of the entire body. I would now reverse this and say that no one should treat the body without some knowledge of the mind. It does not, as the freudians would have us believe, require weeks and months to acquire a sympathetic insight into the problems of the average patient. In the majority of cases the trouble is easily discovered. Those who require more time and greater skill than the general practitioner can furnish should be referred to a neuropsychiatrist and not allowed to drift to the charlatan and the mental healer. The truth contained in the doctrines of Freud, if properly applied, will solve the problem of the charlatan. The error of his doctrines will be eliminated by time and experience.

Fellowship Offered by Johnston-Wickett Clinic—The Johnston-Wickett Clinic of Anaheim are offering to young physicians who have graduated from acceptable schools of medicine and have just completed their intern year, fellowships in the Johnston-Wickett Clinic for one year at $100 per month. The year will be from July 1 to June 30, but they are willing to accept two for the remainder of the present year.

The staff of the Johnston-Wickett Clinic believe that their group is prepared to give young physicians an opportunity to develop their contact in a manner similar to that they would encounter in their own offices. They believe that a year may be spent in one or more of their departments to the advantage of the young physician, and they agree to assist in every way possible at the end of the year's service in helping the man who has completed his work in finding a suitable location. The clinic and staff announce that they will work in full co-operation with the medical colleges and the organizations of medical men in carrying this movement forward.

THE DIAGNOSTIC AND PROGNOSTIC VALUE OF BREATH-HOLDING TEST*

By F. H. McMECHAN, M. D., Avon Lake, Ohio

How long can you hold your breath?

This seems an almost absurd question, and yet cumulative experience is showing that the breath-holding capacity and the apneic pause can be made of the most practical diagnostic and prognostic value in the routine practice of medicine. In simplicity, scope and utility, respiratory tests may be classified with the taking of the temperature, pulse, and respiratory rates.

It is nearly two centuries since Valsalva's classical experiment, in 1740, showed the marked and easily recognizable effect of sustained *forced expiration* on the pulse beat, and therefore on cardiac efficiency, when the respiratory passages are forcibly closed. A hundred years later, in 1838, Johannes Mueller of Berlin added the complementary experiment of the effects on the pulse of *forced inspiration* under similar conditions. These two experiments early indicated the intimate relationship of the cardio-respiratory mechanism in health and disease.

In 1902, Sabrazes, of Bordeaux, collected the literature on the voluntary apneic pause, and in an investigation of his own, by means of a split-second watch, he found the average *normal voluntary apneic interval* (between breaths) to be from 20 to 25 seconds in duration; while an interval of 30 to 35 seconds was exceptional. His further observations showed that the voluntary apneic pause varied in different pathological states, and in *mitral insufficiency with asystole,* it was not in excess of from 5 to 10 seconds.

In making his test, Sabrazes used no preliminary forced inspiration, for apnea, under such circumstances, has it own laws. In mitral insufficiency, after compensation had been re-established by digitalis, Sabrazes found the apneic interval prolonged to from 10 to 15 seconds. Sabrazes also reported that the blood pressure rose during the apneic pause, and that the sign of Muset—oscillation of the head—appeared more noticeable during the pause. Of all pathological conditions studied, tuberculosis showed the least response to the test, as even in advanced cases of pulmonary tuberculosis the apneic interval was not so noticeably shortened. In the study of miscellaneous individuals, Sabrazes found that *deep inspiration* or *involuntary expiration,* might lengthen the pause to from 40 to 50 seconds.

More recently, Binet and Bourgeois of Paris have fixed the average normal interval after deep inspiration at 50 seconds. In the French Aviation Service tests, candidates whose pause was under 45 seconds were deemed unsuited for respiration at high altitudes. Unfortunately, Binet and Bourgeois do not allude to the relation of voluntary apnea to disease, tolerance of anesthesia, or to the prolonged interval in special individuals, such as divers.

In 1914, Stange, of Petrograd, recommended the so-called *respiratory test* as the best indication of the patient's cardiac condition for withstanding operation under general anesthesia. Stange found that average healthy persons could hold the breath for from 45 to 50 seconds, while patients with weak heart muscles could do so but for from 10 to 20 seconds. While Stange seemed to have had no suspicion that the breath-holding test was based on an apnea due to *decreased alkaline reserve,* nevertheless he reported observations on a number of chronic diseases, in which he found the duration of the apneic pause shortened in about the degree in which so-called *acidosis* is known to occur from the results of other observers; notably, Yandell Henderson, especially in his studies of altitude sickness.

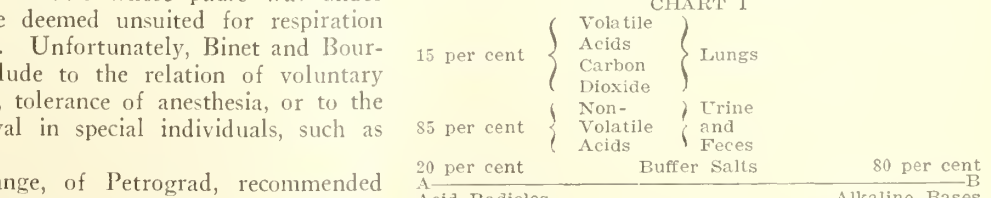
Lewis, Ryffel, Wolf, Cotton, and Barcroft have also shown that the dyspnea of nephritis is due to an acidosis (hypo-alkalinity) essentially like that developed in normal people at high altitudes. Kenway, Pembrey, and Poulton have also found that by following the alveolar carbon dioxide content in diabetics, a warning drop in its tension indicates the approach of coma as long as forty-eight hours beforehand, and much sooner than any other available test.

A thorough understanding and proper evaluation of the breath-holding test, as a diagnostic and prognostic indication in abnormal conditions, depends on the realization that the breath-holding capacity and apneic pause involve the oxygen absorption and carbon dioxide elimination phases of pulmonary respiration as well as the balance of blood and tissue reserve alkalinity. This should be emphasized, especially since Yandell Henderson has shown that three-fourths of the actual breathing of the body is tissue, and only one-fourth pulmonary respiration.

Respiratory alterations, due primarily to disturbances of oxygen absorption, should be classified under the term anoxemia; while those dependent on carbon dioxide elimination should be considered under acidemia; while certain conditions affecting both phases of the respiratory cycle as well as blood and tissue alkaline reserve, should be considered under acapnia. The breath-holding test is all the more valuable, however, because it represents in its ultimate analysis the response of the body to the oxygen-carbon dioxide balance in the alveolar air, blood, and tissues under any and all conditions of health and disease.

Mercur, of Pittsburgh, has recently presented a diagrammatic concept of hypo-alkalinity in relation to disease and the breath-holding test that is very illuminating. He uses the accompanying diagram (Chart I), suggested by blood chemistry studies, to illustrate his therapeutic concept:

CHART I



Imagine all the blood of the body to be represented by the straight line A-B. The blood is a

* Read before the General Sessions of the State Meeting at Yosemite, May 16, 1922.

fluid approximately of 80 per cent alkaline bases and 20 per cent acid radicles—a proportion held in remarkable balance, according to Rowntree, by the *buffer salts* of the blood. In *health* the buffer, irrespective of metabolic indiscretions, promptly takes up an excess on either side, and the delicate balance is not materially changed. When *disease conditions* affect the buffer mechanism, there is an acidosis on the one hand, or an alkalosis on the other—either of which may precipitate serious conditions, especially if either is prolonged or severe.

The 20 per cent of acid radicles represent 15 per cent of volatile acids, thrown off principally through the lungs as carbon dioxide and 85 per cent of non-volatile acids, excreted principally through the urine and very slightly through the feces.

According to Mercur, this diagrammatic concept makes it quite evident that if the non-volatile acids, as a result of *deficient elimination,* accumulate in the blood, the volatile acids will be thereby compressed by the lungs and will have to be increased, and thus the breath-holding capacity will be more or less decreased. This is the rational explanation of the clinical value of the breath-holding test.

It also explains why the breath-holding test may be utilized to *anticipate* the diagnostic and prognostic indications of blood and urine analyses, when retention products are being thrown into the blood stream.

Means further illustrates the acid-base equilibrium in disease by the accompanying formula and diagram, originally suggested by L. J. Henderson, H. W. Haggard, and Yandell Henderson.

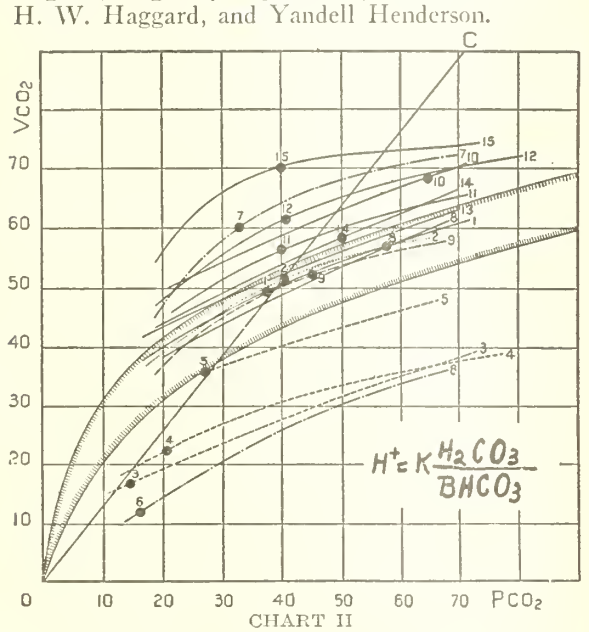


CHART II

The formula is based on the principle that the reaction of the blood is dependent chiefly on the ratio of free carbonic acid to bicarbonate. H^+ is the concentration of ionized hydrogen, H_2CO_3 the concentration of the free carbonic acid, and the $BHCO_3$ the concentration of bicarbonate, and K a constant. The fraction $H_2CO_3/BHCO_3$ ordinarily has a value of approximately 1/20.

Changes in this ratio denote changes in H^+, that is in the blood reaction, while changes in the actual magnitude of the denominator denote changes in available alkali of the blood, and in the numerator changes in the carbon dioxide tension. Knowledge of the two terms of the ratio in any given blood reveal the two most fundamental facts of acidosis.

For clinical purposes Means considers the simplest way of arriving at the value of the ratio, and the two terms of the fraction is to secure data for plotting the so-called carbon dioxide dissociation curve by the method of Christansen, Douglas, and Haldane. Means has found the carbon dioxide dissociation curves of normal human blood to be within the shaded area. When both are normal they cross the line O-C at the points A^1 and A^2, respectively. Any marked change from health to disease would be indicated by a deviation to the alkaline or acid side of the line O-C, or as a response to therapy, and both would be accompanied by diagnostic and prognostic alterations in the breath-holding test, as governed by the oxygen-carbon dioxide reaction of the respiratory mechanism.

The numbered curves in Means' diagram represent plotted carbon dioxide dissociation curves from blood analyses of actual patients, normal (1, 2) or suffering from diabetic acidosis (3, 4, 5), nephritic acidosis (6, 7), pneumonias (8, 9, 10), cebral hemorrhage (11), anemias (12, 13, 15) and tetany (14). The tendency to acidosis and alkalosis is very apparent.

Yandell Henderson's directions for making the breath-holding test are as follows:

1. Sit quiet for five minutes.
2. Take a full, but not too deep breath.
3. Hold it with mouth and nostrils closed.
4. Note time in seconds.

Diagrammatically, and for all practical purposes, a breath-holding test (Stange) of 50 to 70 seconds is above the average normal, while 45 to 50 seconds represents the test of the average healthy person; 35 to 45 seconds indicates beginning acidemia; 25 to 35 seconds, mild acidosis; 15 to 25 seconds, frank acidosis; and 10 to 15 seconds an imperiling acidosis.

According to the apneic pause, split-seconds watch method of Sabrasez, the following intervals represent the same degrees of normality and depletion of alkaline reserve: 30 to 50 seconds, exceptional; 25 to 30 seconds, average normal; 20 to 25 seconds, beginning acidemia; 15 to 20 seconds, mild acidosis; 10 to 15 seconds, frank acidosis; and 5 to 10 seconds, severe acidosis. The difference in time in the two tests is due to the period of time available for the absorption of the deep breath in the Stange test (Chart III).

Involuntary expiration or inspiration during the making of the test, by either method may lengthen the interval, and must be guarded against. The tests may be made more severe by evaluating the average time of several successive tests.

It is of interest also to note, in passing, that

CHART III

Breath-Holding Stange (Seconds)	Sabrazes (Seconds)	Condition	Vital Capacity	Pulse Rate	Resp Rate	Pulse Press.	Heart Load Per cent	Hemoglobin	Oxygen Need Per cent
45-50	25-30	Normal	3500 cc	72	16	40	50	100	20
35-45	20-25	Acidemia	3000 cc	80-100	24	60		90	30
25-35	15-20	Mild Acidosis	2500 cc	100-120	32	80		80	40
15-25	10-15	Acidosis	2000 cc	120-140	40	100		70	50
10-15	5-10	Severe Acidosis	1500 cc	140-160	48	120	200	60	60

the breath-holding test bears a definite and direct ratio to vital capacity as gauged by the spirometer. Dryer and others, notably Wittich, Peabody, and their co-workers, have noted that, while especial fitness and physical training may *increase* vital capacity by 30 per cent above normal, physical fatigue and weakness *decrease* it by about the same amount; *whereas heart disease and other pathological conditions may show a vital capacity 75 per cent below normal.*

Thus, a normal breath-holding test would predicate a minimum vital capacity of 3500 cc. in the average-sized male, and 3000 cc. in the female; whereas, a breath-holding test of 10 to 15 seconds (Stange) would indicate a vital capacity of 1500 cc. or less. As the diseased condition becomes more severe, the breath-holding capacity becomes shorter and the vital capacity falls; and when the patient improves, both again approach normal. Clinically, vital capacity figures bear an approximate relation of 1 to 100 to the Stange test in the male, and the Sabrasez test in the female.

Patients with cardiac disease can lead a normal life if their vital capacity is above 90 per cent; a vital capacity between 70 and 90 per cent means a restricted life and slight amount of work. Patients whose vital capacity is less than 70 per cent are dyspneic on very moderate exertion, and when the vital capacity falls to 40 per cent, dyspnea is pronounced and decompensation is present, or readily occurs.

At this point it should again be emphasized that all *breathlessness* is not necessarily of cardiac origin. A year ago, while discussing the breath-holding test with the physical director of a well-known athletic club, he informed me that he had a group of some twelve business men in his classes, all over forty-five years of age, who got breathless after brief exercise, but on examination by their doctors had been pronounced cardiacly sound. He was at a loss to account for their dyspnea.

Such patients should be given Cornell's tests for the acidemia of chronic nephritis as a prelude to a more searching examination. Cornell has shown that in ninety-five out of one hundred cases, in which nephritis has been present under three years, there is a non-cardiac form of dyspnea associated with mild exertion. His charting of the average respiratory and pulse rate response to exercise in one hundred cases of early chronic nephritis is of very pertinent interest (Chart IV). The tardiness with which the respirations approach their rest-rate is readily seen to be in decided contrast with the quicker and normal slowing of the heart rate.

Cornell has found that although not more than 20 per cent of patients make a complaint of this dyspnea, since in mild cases it is not troublesome, 95 per cent of early nephritics will admit having it when questioned, and its presence can be proved by testing the response of the cardio-respiratory rate-ratio to exercise.

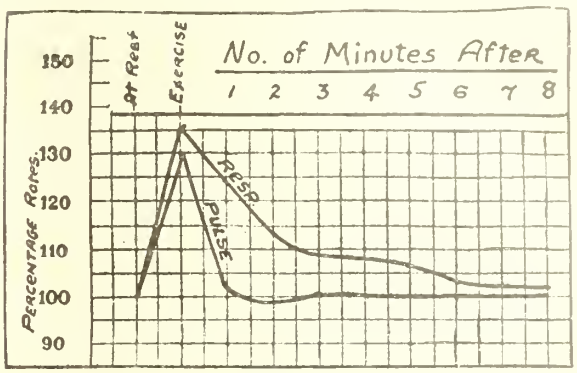

CHART IV

Nephritic dyspnea has two distinguishing characteristics:

1. It has no accompanying cyanosis.
2. It is speedily removed by the oral administration of sodium bicarbonate. Usually, after 4 (20 gr.) doses of bicarbonate, the most extreme type of nephritic dyspnea subsides and disappears.

In fully half the cases studied, Cornell has noted that color changes (red, blue, green or varigated) of the electric bulb are described by the patients during the dyspneic period after exercise, and that alkaline therapy obviates the delusion.

The degree of dyspnea does not always coincide with the *phthalein* output, and seems more dependent on the degree of acidemia and the sensitiveness of the respiratory center. Clinically, this cardio-respiratory test is presumptive evidence of incipient nephritis, even in the absence of albumin, and it also indicates alkaline therapy in nephritics, whose distressing dyspnea fails to respond to digitalis.

Accumulating clinical observations are also showing that the breath-holding test may be charted in relation to pulse rate, pulse pressure, respiratory rate, hemoglobin index, and oxygen need. Some of these relations are briefly shown in Chart V.

CHART V

Case No.	Condition	Breath-holding Test	Pulse Rate	Blood Pressure Sys.	Blood Pressure Dias.	Pulse Pressure	Hemoglobin Index	Oxygen Increase Per cent

13.	Acute Infective Cellulitis	15 sec.	120 (Temperature 102.4°—For every degree above normal temperature the baso-metabolic rate is increased 10 per cent.)					

At the request of the National Anesthesia Research Society, W. I. Jones, secretary of the Research Committee, subjected the daily run of patients coming to his dental clinic for extractions to the breath-holding test, and ten of the cases charted occurred in the first fifty patients examined, while the other three cases included were operated on at the hospital during the same period.

As patients presenting for extractions are commonly considered to be in average health, an incidence of one seriously handicapped patient in every five in so short a series is certainly provocative of thought.

Note the striking difference in the two diabetic cases (1 and 11): the latter with considerable sugar in the urine, and a breath-holding test of 35 seconds, indicating good renal permeability and fair surgical risk for an amputation; the former showing a breath-holding test of 16 seconds and being a very grave anesthetic risk, although walking into the clinic for a simple extraction.

Note the three thyroid cases (2, 3, and 4), and see how the breath-holding test predicates the other reactions of a more searching examination to determine surgical risk and prognosis. Consider the cardiac cases (5, 6, and 7), and contrast the mitral regurgitation patient, whose booming murmur seemingly could be heard across the room, with the more serious anemic and the very grave mitral risk with a heart load of 200 per cent. The breath-holding test again points the finger of warning. The tubercular cases (8 and 9) were anything but good risks for operation or anesthesia, and yet these patients had little or no appreciation of the gravity of their condition. It is also interesting to note the effects of pus, sepsis, and cellulitis on the breath-holding capacity. These relations, clinically noted by Jones, may be diagrammatically presented as in Chart III.

In the recent influenza epidemics it has often been very difficult to make a certain prognosis in broncho-pneumonias. In this connection Bié, of Copenhagen, studied one thousand cases of influenzal broncho-pneumonia and published his analyses, and more particularly his conclusions regarding the 234 deaths in the series of cases. This large loss of life was due in some degree to the fact that many of the women were pregnant, for the death rate is 2.5 times as great in the gravid. There were also fifty-five patients with heart disease in which the mortality rate was very heavy. A toxic factor, as shown by the presence of jaundice, albuminuria, and the behavior of the temperature, pulse and respiration, means a bad prognosis. Bié found that half of those who breathed thirty-four and upward on admission died, while if the respiratory rate was below thirty-four recovery was the usual outcome. This difference was not dependent on whether the pneumonia was single or double, but inhered in each form, although naturally the prognosis is much better for single pneumonia. In all pneumonias with a respiratory rate above 40 the prognosis is grave, and the more rapid the breathing the worse the outlook.

Hirschfelder, of Minneapolis, has recently stressed the explanation why influenzal pneumonia is so fatal. In influenzal pneumonia the cyanosis is not due to heart failure, but is produced in much the same way as is the cyanosis of congenital heart disease, by the entrance of unaerated blood into the left side of the heart. W. C. Stadie has shown that, whereas in ordinary lobar pneumonia very little blood flows through the consolidated area, owing to increased resistance, and most of the blood flows through the normal parts of the lungs, where it is well oxidized, in influenzal pneumonia there is little resistance to the blood-flow through the congested areas. So the blood flows through without being oxidized and thus enters the left auricle, where it is mixed with aerated blood; and so a mixture of blue and red blood is pumped to the tissues. Thus, such cyanosis is not an expression of heart failure, as it is in the ordinary lobar pneumonia, but an expression of the kind of mixed blood which is coming into the heart from the lungs. It can be readily seen from this explanation why the respiratory rate becomes prognostic.

Very recently Gilbert Fitz-Patrick has reported on the results of the breath-holding test in 871 obstetrical cases, primiparas and multiparas of all ages, and including the various complications found before and subsequent to pregnancy.

1. The average parturient woman has a breath-holding pause of 25 seconds (Sabrazes).

2. The shortest breath-holding test, 3 seconds, was found in a primipara, 44 years of age, weighing 180 pounds, who had a cardio-renal insufficiency, with general venous stasis, and who gave a history of rose fever in her younger life.

3. The longest breath-holding test, 65 seconds, was found in a primipara, 24 years of age, who holds the hurdling championship for girl athletes in her State.

4. The average cardio-nephritic pregnant woman has a breath-holding test of 11 seconds.

5. The toxemias of pregnancy due to faulty excretion showed a test of 18 seconds, while those due to faulty secretion showed a test of 15 seconds. The average vital capacity in 180 obstetrical cases was 135 cubic inches.

Fitz-Patrick concludes (1) that the average pregnant woman has a breath-holding test (Sabrazes) of at least 25 seconds. Any reduction below this point demands an explanation. (2) And that the pregnant woman with an apneic pause of 15 seconds has an organic lesion, is a poor obstetro-surgical risk, and should be given an anesthesia only by a professional anesthetist, nitrous oxid-oxygen being the anesthetic of choice, and the individual oxygen need being determined and supplied.

In conclusion, the breath-holding test in connection with the patient's response to other tests, when indicated, may be of diagnostic and prognostic significance, and may not only indicate therapeutic measures, but may also serve as a guiding sign to their effectiveness. Used routinely at the bedside, in the office, and in the hospital, it can be made one of the most valuable assets of daily practice.

(Stop 63, Lake Shore Road.)

INFECTION OF THE PLACENTA*

By J. MORRIS SLEMONS, M. D., Los Angeles

Since the middle of the nineteenth century, when Semmelweiss, Tarnier, Holmes, Pasteur and Lister laid the foundation for modern aseptic surgical technique, the subject of wound infection and its relation to the mother's convalescence after childbirth have been discussed as thoroughly as their importance justifies. The clinical, pathological and bacteriological evidence which has been accumulated leaves no doubt that favorable conditions for infection prevail during childbirth, that precautions are required to avoid such a complication and that, if these precautions are disregarded, the hazard for the mother becomes very great indeed. It is not desirable to detract from the emphasis already placed upon this danger for the mother, but it should be understood that under given conditions there exists also a serious danger for the infant. Bacterial infection during labor may reach the placenta, pass to the fetus and cause its death either before or after birth. This double hazard, obviously, must strengthen our purpose to observe strictly every precaution against intrapartum infection.

Infection of the contents of the pregnant uterus, as Hellendall has shown by animal experimentation, may occur by three routes, namely, first, by way of the vagina; second, by way of the maternal blood-stream; and third, from the peritoneal cavity by way of the Fallopian tubes as in cases of appendicitis.

Although each of these mechanisms plays a role in human pathology, the first mentioned is encountered by far the most frequently. It is observed usually in cases where labor is prolonged after the rupture of the membranes. In these circumstances the amniotic fluid escapes and the uterus retracts, thus reducing the size of the amniotic cavity. Then it becomes inevitable that the amniotic epithelium should have its basal attachment restricted and its contour distorted. The cells change from a cubical to a cylindrical shape; the nuclei are displaced upward and not infrequently are forced out of the cells which perish immediately and are desquamated for longer or shorter stretches. Injuries of this kind clearly impair the protective action of the epithelium and, if bacteria are present, they may pass through the subamniotic connective tissue, enter the fetal blood-vessels which cross the placenta, and thus reach the umbilical cord.

Now, since the placenta receives simultaneously the blood of the mother as well as the blood of the fetus, once bacteria have gained entrance to the placenta, both mother and fetus are liable to infection. Ordinarily the fetus suffers the more severely, because in the case of transamniotic infections its blood vessels are in the more exposed position and through them the bacteria reach the fetal circulation. The walls of the umbilical vessels are promptly attacked and the infection may extend to the Whartomian jelly. The effect upon the fetus varies—a fact which probably depends upon both the virulence of the bacteria and the period of time elapsing between the infection of the placenta and the birth of the infant.

Frequently, the effects of placental infection upon the mother are limited to the period during labor and amount to no more than a mild degree of fever, rarely exceeding 102 degrees, which subsides the first or second day post-partum. On the other hand, it happens occasionally that the infection spreads beyond the placenta to the uterine wall when typical puerperal infection ensues.

The practical importance of placental infection becomes apparent only when the organ is routinely submitted to thorough examination in the laboratory. Fifty-two instances of infection were encountered in 3000 consecutive placentae derived from cases delivered in the hospital and on this basis may be expected once in sixty deliveries. These statistics, however, include a number of patients sent to the hospital as a last resort after protracted labors and frequently after unsuccessful operative attempts to effect delivery. In private practice, the incidence of placental infection, I am sure, is very much less than in institutions to which patients are sent after they have been in the hands of midwives or have had random medical care.

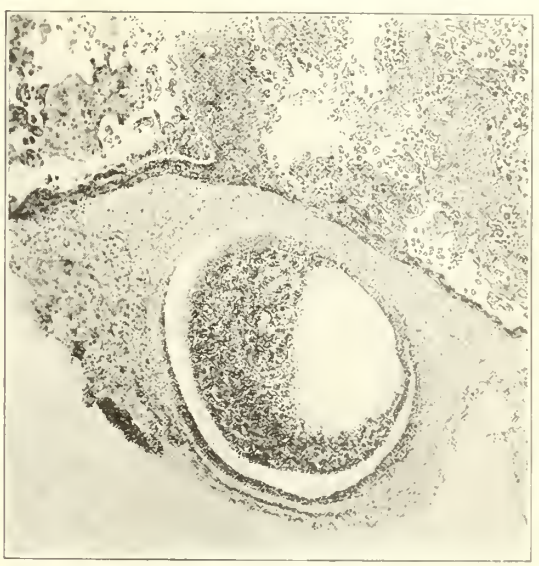

Fig. 1

Thrombosis of blood-vessel on fetal surface of placenta and leucocytic infiltration of subamniotic connective tissue

The ultimate result of placental infection is apt to be much more serious for the infant than for the mother. In my series of fifty-two infected placentae among 3000 cases there were thirty-nine infant deaths, a mortality of 1.3 per cent. Almost surely, however, not all of these deaths may be ascribed to placental infection, for the series included cases of eclampsis, placenta praevia and dystocia, in which operative measures were employed to effect delivery. In such cir-

* Read before the Section on Obstetrics and Gynecology of the California Medical Association at Yosemite National Park, May 16, 1922.

cumstances it is impossible to compute the mortality due to placental infection alone.

Maternal infection was proved during the puerperium in fifteen cases. Fortunately the infection was never a severe one. Generally, the slight degree of fever during labor disappeared after delivery. In two cases, however, fever reappeared on the second and third day post-partum, respectively, and subsequently the course followed was that characteristic of a mild puerperal infection.

The measures required to prevent the infection of the placenta are no other than those most effective for the prevention of puerperal infection. Naturally they include the maintenance of strict aseptic technique during the course of labor —the sterilization of the equipment employed, careful preparation of the patient, conscientious disinfection of the physician's hands and the use of sterilized rubber gloves. It is imperative also to limit the number of vaginal examinations, or better to replace them altogether by rectal ex-

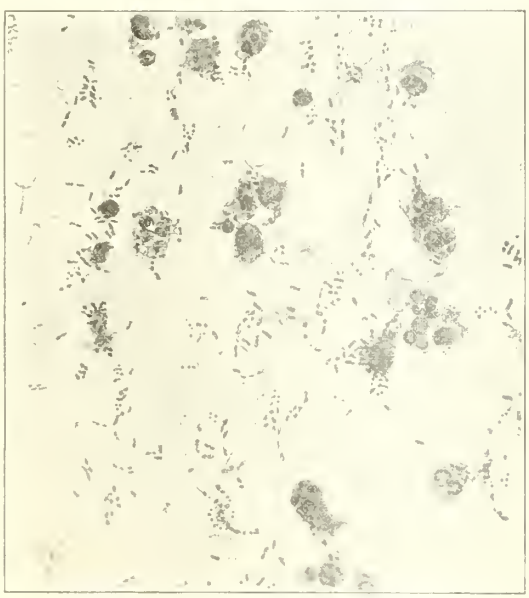

Fig. 2
Bacteria in the subamniotic connective tissue in a case of placental infection

aminations, which after a little practice become thoroughly satisfactory and practically abolish the risk of contaminating the birth canal unless it is necessary to terminate labor by some operative procedure.

DISCUSSION

H. A. Stephenson of San Francisco—I have been very much interested in this paper because Dr. Slemons called attention to this some years ago and since that time we, at the Stanford University Hospital, have paid some attention particularly to this infection of the placenta. In reviewing the cases there, in about 2700 cases I have found about 48 cases of infection. The type of infection is not given inasmuch as we relied entirely on the presence of inflammatory exudates rather than staining these sections for the presence of bacteria. I cannot tell you exactly the number of babies who died in this series of cases, but I think that, off hand, Dr. Slemons' figures would about correspond to ours. I question somewhat, congenially, because Dr. Slemons is a former teacher of mine and I still respect his judgment, the fact that finding cylindrical epithelium over the surface of the placenta is a definite evidence of infection either beginning or more advanced. In the routine study of placentae I am of the opinion that a large percentage of them, even in cases that show infection of the amnion they are infections of the placenta. The fact he has mentioned, of finding cylindrical epithelium in the amnion, I believe that the amniotic may vary normally in shape.

I would also like to emphasize with Dr. Slemons the importance of infection in relation to the baby as well as to the mother and we limit, therefore, vaginal examinations as much as possible. That also applies, I think, to long labors. We try not to have patients stay in labor any longer than absolutely necessary. Even in teaching hospitals we have been very conservative about that. I can recall a good many cases where patients have been in labor thirty to forty hours when perhaps today we might see an indication for terminating the labor more promptly. It is also, I think, important to subject every placenta and cord to miscroscopical examination. That has been done routinely at our hospital for a long time now and not only do we pick up cases of infection unexpectedly but we also pick up other conditions. Some cases in which the mother does not show evidence of syphilis we do find very definite evidence in the placenta, and I think it then advisable to subject both the patient and her husband to an examination of the blood. There are a good many other interesting things which have come up with these examinations of the placenta but I would like to impress this point in addition to looking for evidence of infection.

J. Morris Slemons—I appreciate Dr. Stephenson's remarks and it occurs to me that I did not make myself quite clear. In the first place I did not dwell very much on but merely mentioned the fact that the placenta may become infected in other ways. I did not dwell on these because I did not want to fasten your attention on other things. In a recent case I found that the mother had appendicitis. I operated on the abscess but the product of conception was infected and the fetus died. Evidently that is one way in which infection may occur. Again we all know that the blood stream may infect the placenta. My view with regard to the change in the epithelium is that you can not get an infection through the intact epithelium. The fact that we can get infected placentae in other ways I am more than willing to admit but I do feel very strongly that the damaged epithelium produces a portal of entry. It probably would be interesting to add just a word about the symptoms which the infant presents when it is infected under these circumstances. They are by no means the same. In one case, the child had bleeding from the cord, nose and mouth. In another, there was peritonitis and if we had not examined the placenta as a matter of routine we would have said that the child died from an infected cord, but having shown streptococci in the placenta we know that the cord had nothing to do with it. Again a child died of pleurisy on the tenth day and in this instance bacteria were found in the placenta.

It seems to me that recognition of these cases will go far toward explaining a good many of the infant deaths which heretofore have gone entirely unexplained.

TORULA INFECTION *

REPORT OF TWO CASES

By NEWTON EVANS, M. D., Loma Linda
(From the Laboratory of Pathology, College of Medical Evangelists)

The name "torula" or "pseudo yeast" is applied to a group of organisms resembling but not identical with true yeasts and multiplying only by budding. The first spontaneous infection with torula was noted in a horse in 1902 (Frothingham). The first human infections with this organism, recognized as such, occurred in 1914. These were two cases observed at the Peter Bent Brigham Hospital in Boston and described by Stoddard and Cutler in a monograph published in 1916. They gave the name "torula histolytica" to their micro-organism and discovered in the literature accounts of four additional cases occurring previously, which were manifestly of the same type. Since the publication of Stoddard and Cutler's monograph there has been one additional case reported by Pierson of San Francisco, making a total of seven. I am now reporting two other cases.

There are points of resemblance between the lesions of *torula* disease and those of systemic *blastomycosis* or *oidiomycosis* and *coccidioidal granuloma,* as well as between the organisms themselves. These relationships suggest a consideration of these three types of infection as a group of infectious granulomata, to be compared, and points of difference pointed out.

A large proportion of the cases of *coccidioidal granuloma* have been fatal, as have practically all the cases of systemic *blastomycosis.* All of the *torula* infections so far recognized have terminated fatally. The great majority of the patients dying with systemic *blastomycosis* have been observed in the central portion of the United States, particularly about Chicago. Practically all of the infections with *coccidioides* have occurred in California, the earlier cases coming principally from the San Joaquin Valley, but more recently a large number being observed in Los Angeles and adjacent territory. Of the nine cases of *torula* infection recognized, two occurred in Europe. Three have occurred in California, including the two herewith reported.

With reference to the morphology of the organisms of these three diseases, they are all of very large size as compared with the ordinary bacteria. Of the three the *coccidioides immitis* is the largest, being from 5-85 mikrons in diameter. In the tissues it is spherical and multiplies only by sporulation, large numbers of small organisms escaping from the ruptured capsule of the parent organism. The *blastomyces* is also perfectly spherical in shape and varies from 4-20 mikrons in diameter. In the tissues and lesions in contrast to the *coccidioides,* it multiplies only by budding, like the yeasts. The pathogenic *torula* is somewhat smaller (1-13 mikrons in diameter), is spherical or oval in shape, and in the tissues multiplies only by budding, resembling the *blastomyces* in this respect.

When we come to observe the manner of growth in artificial media of each of these three pathogenic micro-organisms we find some very striking peculiarities. They all grow very readily on the ordinary nutrient media. But in the case of *blastomycetes* and *coccidioides* the form of the growth is entirely different from those in the tissues, appearing now in the form of a luxuriant mass of long branching mycelia, much like ordinary molds. The artificial growth of the *torula,* however, differs from that just described, and consists of forms practically identical with those seen in the tissues, having no resemblance to the molds, and consisting of yeast-like budding organisms.

DISTRIBUTION OF LESIONS

In all the human *torula* infections reported the lesions have had a decidedly characteristic distribution, having been invariably found in the central nervous system and less constantly in lungs, liver, spleen, kidneys and lymph nodes in addition to the brain lesions. No lesions of bones or of the skin have been observed, differing in this respect from the two related diseases.

In all cases the symptoms referable to the central nervous system dominated the clinical picture, indicating organic brain disease. Such clinical diagnoses as tubercular meningitis, senile dementia, general paresis and intracranial pressure symptoms resembling those of brain tumors, were made in these cases.

In all cases the pia-arachnoid was affected by a chronic leptomeningitis, which was associated with more or less extensive inflammatory and caseous lesions of the brain tissue itself. Apparently the infectious process extended from the meninges into the brain tissue by way of the perivascular lymph channels. There is a marked tendency to an involvement of the ventricular lining with a consequent internal hydrocephalus.

Microscopically the lesions are chronically inflammatory with the accumulation and formation of giant cells, large round cells and plasma cells, with intracellularly placed organisms, but practically no polymorphonuclears. There are extensive areas of caseation and the formation of fibrous tissue in the lesions.

The organisms themselves multiply in the tissues, as in artificial culture, only by budding. Several buds may occur simultaneously on one organism and organisms of any size may have buds. In some of the lesions the organisms are of large size, in others they are very small and difficult to recognize by microscopic examination.

One of the most striking characteristics of the lesions is the large amount of mucinous material which most of them contain. This evidently is a product of the growth of the parasite, each organism as it appears microscopically in the tissue being surrounded by a little circular zone of the homegenous, clear and slightly basic-staining mucin. As the organisms invade and grow in the tissue, often intracellularly, the tissue is dissolved and replaced by the organisms and their covering of mucinous material, with a surprising

* Presented to the Section on Pathology and Bacteriology of the State Meeting at Yosemite, May 17, 1922.

lack of any signs of inflammatory reaction. This is notably seen in the tissues of guinea pigs, inoculated experimentally. This destructive action of the parasite upon the tissues is the reason for its name as applied by Stoddard and Cutler, "torula histolytica."

CASE REPORTS

Case 1—Mexican boy, 13 years of age. Entered the medical service of the White Memorial Hospital, Los Angeles, September 15, 1920. Mother states boy's previous health had been good; also that he had been accustomed to take quite regularly and in large quantities a Mexican drink called tesquino, made by fermenting corn with yeast. Patient had mastoidectomy when five years old, and pus was discharged from wound in large amount for one month.

The family history is unimportant. A sister has had a chronic infection of some nature affecting the backs of the hands at times for the past two years.

Present illness began with persistent headache nineteen days before admission to the hospital. During this time he had been brought from Arizona to Los Angeles, and had been seen by a number of physicians. The headache began with pain at the bridge of the nose and later was centered in the frontal region, gradually spreading over the temporal regions. A swelling on the right side of the neck developed, but this did not soften or break down. It was evidently a cervical adenitis. He has slept poorly during the course of the disease.

Physical Examination: Stiffness in the posterior cervical muscles; is unable to flex the head. There is a notable wrinkling of the skin of the forehead; upper extremity reflexes present. Patellar reflex absent; ankle clonus not obtainable. There is a positive Babinski. Kernigs and Brudzinski signs present.

The patient lies in bed moaning with pain. Clouded mentality, eyes closed, presumably from photophobia. Pulse 54, blood pressure 98 and 64.

Repeated spinal punctures were made while in the hospital. Cerebrospinal fluid was under considerable pressure and slightly cloudy. All specimens showed almost complete absence of polymorphonuclears with only a few lymphocytes and occasional endothelial cells. Wasserman negative in cerebrospinal fluid. The Noguchi globulin test was slightly positive.

The most notable findings in the spinal fluid was the presence of numerous yeast-like budding organisms. These organisms were counted as follows: September 15, 320 per cmm; September 16, 480 per cmm; September 21, 840 per cmm; September 22, 1120 per cmm; September 28, 2400 per cmm; October 3, 2200 per cmm.

Nasal smears showed the presence of a few yeastlike organisms similar to those in the spinal fluid.

The only abnormality noted in the urine was a trace of indican.

Blood: Hemoglobin, 50 per cent; red cells, 4,000,000; white cells, 7200; differential count within normal limits.

Course of Disease: The patient rapidly grew weaker and more emaciated. Following each spinal puncture the headache was definitely relieved for about forty-eight hours. Became semicomatose, responding to questions only at times. On October 4, pulmonary edema developed and death occurred on October 5.

Autopsy was refused.

The following notes regarding the organisms appearing in the spinal fluid were made at the time of the examination by H. E. Butha, who made the laboratory examination in this case.

Organisms are present in large numbers in fluid, some round and small, about 5-10 mikrons, others quite large, and round or slightly elliptical, many present showing a bulging point to one side. All have a double refractile contour and show buds of varying sizes, some very small, others being as large as parent cell. Some smaller cells are found budding as well as those of medium and large size. Few prominent granules present in the cell bodies. Budding occasionally is present in two directions, and three or four organisms may be attached together.

Cultures: Organisms grow readily on ordinary media, such as plain agar, blood agar, glucose agar and bullion broth. Colonies appear in from twenty-four to forty-eight hours. No mycelial formation, and no spore production noted. No fermentation occurred in sugar media.

Rabbits were inoculated intraperitoneally and intravenously and killed after four weeks. Multiple lesions containing the parasites were found in various organs and notably in the meninges and brain tissue after intravenous inoculations. Guinea pigs were inoculated intraperitoneally and killed after four weeks. Multiple lesions were produced in various organs, the most characteristic being in the testes. These are gelatinous and translucent and microscopically show immense numbers of the budding organisms surrounded by the gelatinous material with very little delicate fibrous tissue and cells between the organisms, practically no cellular exudate being present. The meningeal and brain lesions are chronic inflammatory in character with many small round cells and numerous immense foreign body giant cells.

It is regretted that it was impossible to secure permission for an autopsy in this case.

Case 2—Hospital Case No. 5965. Patient referred to White Memorial Hospital by Dr. Claude E. Steen. Mexican woman, age 20; married.

Family History: One brother died at 1 year, one sister died at 2 years, one sister living.

Personal History: Whooping cough in early life. Enlarged cervical lymph nodes removed at 14 years of age. Married at 18 years. One pregnancy, terminated at seven months, living child. Again pregnant, six months.

Present Illness: Began having frontal headache and pain in eyes of moderate severity March 19, 1922. On May 1 there was severe frontal headache in right temporal region. May 2, headache worse and violent vomiting. May 3, headache still worse, vomiting and photophobia. May 8, severe headache and photophobia, slightly rigid neck, patellar reflexes diminished. Temperature 99.8. Pulse 100. Extreme constipation. On this day lumbar puncture was made—25 cc. of comparatively clear fluid escaping under increased pressure. Pain in the head was immediately relieved, patient walking from physician's office.

The pain gradually returned, until symptoms on May 11 were the same as preceding the spinal puncture. May 11, temperature 98, pulse 72. At this time the knee jerks were markedly exaggerated. A second spinal puncture with the removal of 35 cc. under increased pressure again gave relief from the symptoms. Blood pressure S110, and D75. May 12, patient felt much better.

Microscopic examination of fluid reveals 35-40 characteristic budding organisms in the cubic millimeter, with increased lymphocytes, but no polymorphonuclears. Cultures on the usual media yield characteristic colonies of the torula organism.

Spinal punctures were made as follows: May 8, 25 cc., clear fluid, 35-40 organisms per cmm. May 11, 35 cc., slightly cloudy fluid, 160 per cmm. May 14, 40 cc., slightly cloudy fluid, 360 per cmm. May 18, 35 cc., slightly cloudy fluid, 1800 per cmm. May 21, 40 cc., fluid not examined.

Blood Count: May 24, red cells, 3,568,000; white cells, 13,200; hemoglobin, 73 per cent—

blood and spinal fluid Wassermann, negative. Urine shows trace of indican only.

The condition rapidly grew worse and on May 2 the patient was removed to the hospital, but as no improvement was noted the friends took the patient to her home on May 26, where she died on May 27. It was not possible to secure permission for an autopsy.

The most notable feature in the examination of these patients was the finding of immense numbers of the torula in the cerebrospinal fluid by direct microscopic examination and the securing of a pure culture of the characteristic organisms on artificial media.

It seems from an examination of the reports of the seven previously reported cases that in none of these were successful cultures secured from the fluid obtained by spinal puncture, although in one case organisms having the characteristic morphology were seen.

Attention should be called to the danger of failing to recognize the presence of these organisms in the direct microscopic examination of specimens of spinal fluid on account of their superficial resemblance in size and shape to lymphocytes.

The recognition within a comparatively short period of these two cases with characteristic symptoms and having the specific organism in the cerebrospinal fluid, as well as the fact that the organism may easily be overlooked, would lead one to suspect that this type of meningeal infection may be of fairly frequent occurrence and be escaping discovery.

CONCLUSIONS

The torula infection on account of its peculiar localization in the meninges and its characteristic symptomatology may justly be looked upon as a clinical entity and a specific infectious disease.

It is important in cases with intracranial and meningeal symptoms of unknown nature to carefully examine the cerebrospinal fluid by direct microscopic examination and by cultural methods.

Relapsing Fever in California—LeRoy H. Briggs, San Francisco (Journal A. M. A., September 16, 1922), reports the cases of a man and his wife who, while camping in California, were probably bitten by some suctorial insect, presumably a bedbug or a tick, although this cannot be proved. In each case, eight days later, a paroxysm of chills, fever, malaise and prostration ensued and lasted three days. In the case of the husband, three relapses occurred, each more severe than the preceding. With the wife, two relapses occurred, also of increasing severity. During the four observed paroxysms, spirachetes were found in the peripheral blood in increasing numbers. Intravenous injection of 0.45 gm. of neo-arsphenamin promptly terminated the infection in both instances.

THE RELATION OF THE SURGEON TO THE ANESTHETIST*

By SAXTON POPE, M. D., San Francisco

As a matter of fact, anesthesia was forced upon surgery by a rank outsider, and so it seems to be ever since.

Preoccupied with the problems of visceral pathology and the means to remedy them, the surgeon's mind has worked more with the faculty of contrivance than the comfort and safety of his patients.

In the very essence of things, it is more important to him that he should achieve his objective than that the patient should be made comfortable during the journey. Ordinarily he is not interested in the subjective reactions of the client, only the clinical.

Through custom, the surgeon has come to accept the necessity of anesthesia, partially because it assists him in his work. But you can see even today the viewpoint of the average operator to whom anesthesia is a necessary nuisance. He stews and frets until his patient is ready for the knife, while the subservient assistant struggles with the powers of darkness and holds the trusting subject in a state of vital suspension between heaven and earth.

The anesthetist having achieved this miracle of physiologic juggling, the surgeon then bullies him for the slightest variation of balance.

During the progress of the operative readjustment, a hundred acts of surgical vandalism may be committed, each with its special, painful, shocking result, and yet the patient must not wince, nor flutter from the normal.

The opportunities for trauma are infinite in variety. From the first cold dash of alcohol and ether on the skin, through an endless series of destructive insults, to the final freight handling change from the operating table to the stretcher, the patient must be protected by a veneer of analgesia—and the anesthetist is responsible.

Consider some of the other adventures of this somnolent victim:

Lying on his back in a position well calculated to throw his sacro-iliac joints out of commission, his arms strapped to his sides, his neck in a posture inviting cervical fracture, the assistant surgeon leaning heavily on his chest or hanging on to an elevated leg, unconsciously attempting to dislocate the hip joint, he winds up by being a fit subject for a chiropractor.

The surgeon is late as usual, deliberates and makes up his mind what he wants to do; shall he do his latest operation and add another successful case to his series, or shall he take the proffered opportunity to discover what really is the matter with the patient and have to worry about the means to correct it.

If he is an intrepid surgeon, he then rushes at his task. Let us not critically down them all for these little slips in technique that require so much time to repair—accidents will happen in the best of families, and let us not broadcast it that such things are possible in modern science; but you

* Presented to Section on Anesthesiology of the Medical Society of California, May 16, 1922, at Yosemite National Park.

know, and I know—in spite of the fact that I am an alleged surgeon—what one might call an imminent surgeon. We shall not advertise our mistakes, but confess them only to our charitable equals, knowing that no matter how bad we may be, our critics undoubtedly are very much worse.

The great thing is that we are here dealing with human life instead of pancakes—and not even the best cook can make 100 per cent successful hits on a pancake. There is no surgeon without his faults and his faux pas. The best thing we can ask of our man is that, when he has us on the table, exposed to public view, that he will treat us like a friend, and not like an enemy or a cadaver.

And there lies the soul of the matter, let him remember that he is dealing with the most wonderful phenomena of the universe—life itself. In his hands are placed the fragile beauty of existence. One false move on his part and it disappears forever. How is it that this remarkable adventure is possible? The arbiter of this state of surgical privilege is the anesthetist. Without the volatile cup of Lethe, surgical operations would be unutterable crime.

Pardoning our blunders and humbly confessing our dependence upon the agent of oblivion, let us see what are our mutual relations and obligations.

In the first place, the anesthetist is entitled to that courtesy offered a consultant. She or he is an equal—in that these two must share the responsibility of conducting the patient safely through an episode of questionable outcome.

One must handle the mechanical problems of surgical procedure, the other must gauge the factors of safety, induce an unnatural and more or less dangerous period of suspense, and meeting every possible emergency of physiologic discord, conduct the human organism back to conscious activity. It is no small or elementary task. It requires that the anesthetist shall know intimately the most subtle functions of the brain, a knowledge of the gross reactions of respiration, cardiovascular phenomena and the surgical complications incident to the occasion, are but the bare essentials of his requirements. He must be wise in the psychology of the pre-operative stage, keen in his intuition of personal idiosyncrasies, and abnormal response. He must gauge the temperament of his patient. Incidentally, he must be able to check up the internist on the functions of the heart, vital capacity, renal elimination, blood dycrasiae, cerebral lesions, and a multitude of other factors having an important bearing upon the problem of narcosis.

It is essential that the anesthetist know the approximate nature of the surgical operation proposed. He must also know the severity of it, the time factor and, incidentally, the character of the surgical chief and his type of work. The anesthetist must choose the anesthetic, because he is responsible for the outcome of this feature of the problem. No stereotype narcosis exists which is suitable to all somatic conditions and varieties of surgical maneuver.

During the progress of anesthesia, the anesthetist, like an engineer in a great steamship, must watch a score of indicators and, through a fundamental knowledge of physiologic phenomena, be able to interpret the slightest deviation from the stage of safety. No routinist, no tyro, no cocksure, innocent and blissfully ignorant neophyte should conduct this department of intelligence.

Each phase of a surgical operation differs in the necessary depth of anesthesia, and as the periods drag out, the saturation of the patient increases, his resiliency departs, where fatigue of the operator, the anesthetist and the patient all must be counted on, then the anesthetist must use rare good judgment in the conduct of the situation. As the operator undertakes each special manipulation, the anesthetist must anticipate it with an appropriate counter move—whether it be deeper narcosis, more air, rebreathing or increased intra-thoracic pressure.

It is the duty of the surgeon to forewarn the anesthetist of any departure from the routine, of any delay or prolongation of the seance.

And he must stay within the bounds of surgical anesthesia.

There is a zone of legitimate activity in surgical work; there are areas and systems that may not be invaded, and there are narrow outer boundaries of anesthesia over which the operator shall not trespass. Over this domain the anesthetist must stand guard, and, as the evidences of trauma are registered on the sensitive indicators of his conning tower, he must sound the note of warning and protest.

Here the dictatorship of the surgeon ceases, and the authority of the man who guides the destinies of cerebral and vascular control must supersede. Again they are consultants, and equals. There can be no dominance of master over assistant.

But in the absence of these untoward episodes in the progress of a surgical operation, when all runs smoothly and safe as it usually does, there is no question of leadership but perfect co-operation and peace, marked by the utmost courtesy and mutual regard. This insures the patient against the dangers of an irritable surgeon and a perturbed anesthetist.

And what excuse have I for these trite phrases; what apology for telling you what you already know? It is this that, as you patiently sit through the dreary hours of serving and saving while other men display their egotism and claim the glories, I want you to know that there are surgeons who recognize your value and your independence, that when we stop to think, we acknowledge your part is as important as ours, and in the mind of the patient often overshadows it.

On behalf of surgeons, I want to pay homage to our co-partners in service to humanity.

(Butler Building.)

California Association of Medical Social Workers—This association has outlined a course of intensive study and round table conferences upon the following subjects: (1) Housing and Immigration Law, (2) Children's Aid Law, (3) Industrial Accident Insurance, (4) Study of Case Work. The study group meeting will be held in the assembly hall of the Children's Hospital Nurses' Home, San Francisco.—Edna Shirpser, Secretary-Treasurer.

POST-INFECTIOUS OR EPIDEMIC ENCEPHALITIS*

REPORT OF THE TREATMENT OF A GROUP OF CASES BY THE INTRASPINOUS INJECTION OF THEIR OWN BLOOD SERUM.

By ROSS MOORE, M. D., Los Angeles

The first case seen by the author during the present epidemic developed in the wards of Base Hospital No. 214 at Savenay, France, in January, 1919.

A year ago I had seen a sufficient number of cases to be able to group them roughly into four clinical classes. (1) Fulminating and quickly fatal cases, (2) acute cases terminating after a few weeks in fairly complete recovery, (3) slowly developing cases ending in chronic disease syndromes, (4) cases more or less chronic in which the symptoms show a tendency to come and go.

This fourth class interested me particularly because it seemed reasonable to suppose that in it the pathological condition must be one of irritation or poisoning rather than destruction.

The second class of cases, those ending in a fair degree of recovery after a few weeks or months, was considered also as being primarily toxic or irritative. It occurred to me that if I could in some manner stimulate the powers of resistance of the affected parts of the brain in these so-called toxic or irritative cases, I might start the process of recovery or at least help it along. Unfortunately this idea was developed at about the time our local epidemic began to wane. Only a few cases have, therefore, come under observation in which it was possible to carry out this experimental treatment.

Eight cases compose the series. Thirty-nine treatments were given in all. The highest number of injections in a single case was eleven. The technic in general was as follows:

A sufficient amount of blood was taken from the patient to give 30 cc. of serum. This was treated in the usual laboratory way to prepare it for injection. In some instances the serum was inactivated and in others not. It was then injected intraspinously after an equal amount of cerebrospinal fluid had been removed. These injections were repeated at intervals of four to twenty days. Their repetition depended on the clinical symptomatology developing after each injection. The first and in some respects the most interesting case came under my observation May 24, 1921.

CASE REPORTS

Case 1.—Mr. J., age 34, married, two children. Referred by Dr. J. H. Edmiston, Los Angeles.

Complaint:—Nervous breakdown and fatigue. Wants to lie down constantly. No ambition. Does not sleep well. Tendency to yawn occurring in spells especially when lying down. Also spells of coughing not associated with throat or lung pathology. Attacks or Diplopia of irregular severity and duration.

Inquiry into history shows that these symptoms have existed in varying intensity for eighteen months dating, as patient believes, from a chill one night. Influenza in the first epidemic of 1918-19. Was two months recovering from it.

Family history not important.

Examination:—Examination shows normal weight and state of nourishment. Tremor of hands and tongue. Deep reflexes exaggerated. Relative left facial weakness. Fundi show no pathology. Pupils small and mobile. Spinal fluid negative for cells, Butyric and Wasserman. During examination patient complains of muscular twitching all over body but none visible to examiner. Patient hopeless and very irritable.

Excerpts From Daily Clinical Notes

June 4 (nine days after first examination)—When out of bed patient wants to sit or lie down all the time. Considerable retardation of initiative. Muscular action slowed up. Facial expression somewhat masklike.

July 1—Above conditions noted as being deepened.

July 18—Patient has become quite sluggish. Stays in bed. Frequent coughing and yawning spells day and night. Spinal drainage performed.

July 19—Patient slightly brighter, possibly as a result of spinal drainage.

July 25—Patient lapsed into former condition. Masklike face. Lead-pipe rigidity which, however, can be quite overcome by voluntary effort. This rigidity returns at once when attention goes elsewhere.

August 1—Spinal drainage with slight passing amelioration.

August 5—Twitching of right face noted. Not constant. Double ankle clonus and Babinski. Also not constant. Marked lethargy and drooling. Wife and friends considered patient much worse than ever before.

August 6—Lethargy much deeper. Taken to Hospital.

August 8—Injection of 28 c. c. of 60 per cent inactivated serum.

August 9—Slight pain in back and legs. Patient quite bright and alert. Demands to be taken from Hospital. Rigidity and lethargy markedly lessened.

August 13—Injection of 20 c. c. straight serum.

August 14—Patient much brighter. Moves, talks and smiles without retardation. Lead-pipe rigidity much reduced. Marked absence of former muscular tension. Twitching in right face continues.

August 18—Injection of 30 cc. inactivated serum.

August 20—Patient up and about with further reduction of symptoms.

August 21—Danced two or three times.

September 14—After three weeks at home, patient returned with appearance of having slipped back somewhat. Was given 30 c. c. of straight serum.

September 15.—Up and about. Better.

September 25—Had a fainting spell. 30 c. c. straight serum.

September 26—Much relaxed. Up and about.

October 1—Frequent attacks of momentary syncope and of yawning.

October 7—30 c. c. straight serum. Slight reaction for the better.

October 11—Spinal drainage.

October 29—General condition same as for two or three weeks. Patient refused to remain in Los Angeles longer and returned home.

A recapitulation of this case shows a condition

* Read before the Fifty-first Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May, 1922.

in which a diagnosis of Encephalitis was reasonable. During the first weeks of observation there was an increase of symptoms to such an extent that the patient's life was despaired of. Spinal drainage during this time had no effect on symptomatology. Both history and observation revealed a marked tendency for symptoms to disappear and return.

Six intraspinal injections were given over a period of two months.

Following each of the first three of these injections a marked amelioration of symptoms occurred so that the patient changed from being bedfast, sluggish, rigid and apparently progressing toward the end of his life, to being able to take part in a dancing party. This improvement did not occur steadily but always following intraspinal injections. Three more injections made after an absence of three weeks provided temporary relief only. The patient became increasingly hard to manage and finally went home. His present condition is reported to be somewhat better than during the eighteen months previous to the treatment.

The most striking features of this case are, first—the coming and going of symptoms, such as diplopia, yawning, coughing, sleepiness and insomnia; second—the apparently causative relationship of intraspinal injections to what was actually spectacular although temporary recovery.

Case 2—Mrs. K., age 43. Referred by Dr. Marcia Patrick.

Mental confusion, motor instability, speech defect and condition of the deep reflexes made a clinical picture suggesting Paresis. History and serological findings pointed away from this conclusion. Encephalitis was diagnosed after a few days' observation.

Acute gall bladder drained ten days after first observation.

Patient recovered sufficiently both surgically and medically to be sent home.

Symptoms returned fifteen weeks after first observation.

30 c. c. inactivated serum used without any noticeable result. Death in two weeks after recrudescence of symptoms and eleven days after serum injection. Diagnosis confirmed post-mortem.

Case 3—S., age 54. Referred by Drs. Adams and Thuresson, Riverside, California.

History—Serious illness of undetermined nature but with temperature, in January, 1920. A second like attack six months later. From date of first attack patient has never been well but has gradually slipped into his present condition.

Examination—Patient shows a Parkinsonian syndrome with definite psychic rigidity and lacking usual agitans tremor.

Was given a series of two inactivated and nine active serum injections over a period of three months. Went home somewhat improved in speech. Could feed himself and roll over without assistance. Initiative definitely improved. Muscular rigidity unimproved.

Case 4—K., age 43. Referred by Dr. Wm. A. Edwards, Los Angeles, Calif.

A quite typical Parkinsonian syndrome of long standing and with a history of Influenza two years ago.

Received two intraspinous injections of his own serum, but would not remain in hospital and was lost sight of. Probably no improvement.

Case 5—Mrs. H., age 43. Referred by Dr. Rae Smith, Los Angeles, Calif.

A typical Paralysis Agitans without history of infectious disease. Shaking began directly after terrific fright in burning building in 1919. This patient had observed the progress of Case 1 so was willing and anxious to try the treatment.

Was given three injections of her own active serum.

Patient was of sanguine hopeful nature and insisted she was much relieved of her feeling of tenseness, especially for two or three days following each injection. No objective improvement noted.

Case 6—S., age 38.

Typical Paralysis Agitans beginning six months after Influenza in 1918.

Five injections of active serum in November and December 1921, three years after Influenza and two and one half years after first symptoms.

Both wife and patient himself noted improvement in certain symptoms that had steadily progressed in intensity for a year or so previously. This improvement was temporary.

Case 7—T., age 34. Referred by Dr. Roy Thomas, Los Angeles.

Fairly typical Paralysis Agitans with coarse tremor, rigidity, mask face, drooling, high pitched voice and spasmodic speech.

Influenza in November, 1918.

In October and November, 1921, was given four intraspinous injections of his own active serum. Drooling entirely stopped. Handwriting better.

Case 8—Married. Age 49. Mine foreman.

Complaint: Tremor in right arm.

History: Light attack of influenza in 1919. History otherwise negative. In 1917 right hand began to tremble and the movements became slow. No pain or loss of muscular power.

This patient was seen first in 1920 and given the ordinary treatment for paralysis agitans with no real relief. In June, 1922, he came back to Los Angeles. At that time examination showed an intensification of the Parkinson type of symptoms in the right hand and with a masklike rigidity of face. Cerebrospinal fluid was negative to all tests. During the period from June 22 to August 24, 1922, he received a series of seven intraspinous injections of his own serum. He returned to his work in much better general health, with a definite relaxation of his facial expression and with a small but definite betterment in control of right hand and arm. After each injection his hand was very much steadier for from two to five days. This was noticeable both subjectively and objectively. The patient was a very commonsense person who was not likely to become enthused and, therefore, see improvement when there was none. The improvement in both facial expression and in his hand was noticeable to many persons who saw him constantly during the period of treatment.

Diagnosis: Parkinson's Disease.

Recapitulation: A typical case of Parkinson's disease which had existed for upwards of five years with a gradual tendency to get worse was treated by this method with some apparently permanent results and very marked temporary amelioration of symptoms.

In this series of eight cases there were three in which a definite variability of symptoms appeared. The other five cases had unchanging or gradually progressing symptomatology. In five cases certain changes noted following treatment seemed to be due to the treatment. No cases were cured. The only case that could reasonably be called acute was No. 2, a woman of forty-three, whose first symptoms appeared three months before this treatment was given. Her condition was desperate when the single intraspinous injection was made. She did not react badly to the injection but died of her encephalitis eleven days after its use. Serum intraspinously seemed to have had no influence either for good or bad in this case.

In the first case there was little room to doubt that the remarkable improvement manifest after

each of the first four injections was directly due to the treatment.

In Case 3, a Parkinsonian syndrome that showed variability in symptoms, definite improvement manifested itself gradually throughout the whole course of injections. An improvement, temporary to be sure, but vouched for by the wife of the patient, a graduate nurse, as being different from any changes she had noted during the many months of previous illness. Although this patient was a born pessimist, he realized his own improvement at the time.

The amelioration of symptoms following each injection given in the Agitans case (Case 8), together with the more or less permanent betterment at the end of the treatment, should be interpreted as indicating that symptoms in Parkinson's disease are not necessarily due to destruction of brain tissue, however long they may have existed.

So far as these particular individuals are concerned no certain permanent benefit has resulted from this treatment. However, some interesting speculations may be indulged in when the general subject of acute or infectious or epidemic encephalitis is considered in the light of this experience.

There must be a time during the course of encephalitis when the disease is attacking the central nervous system, but before actual destruction of brain tissue has occurred. It is reasonable to suppose that this period may be marked by variability of symptoms.

If the therapist could seize the psychological moment when nature needed but a little reinforcement to gain a victory over the encephalitis and throw in just the reinforcement needed he would indeed be the proper ally for nature. It would seem from Case 1 that the patient's own blood serum almost provided this reinforcement. The failure to cure may have resulted from the fact that the brain tissue itself had been subjected to insult too long or that a stronger reinforcement was necessary. I have considered using a foreign serum or the mixing in of a chemical irritant such as mercury or arsenic, but have not done so as yet. The fact that in Cases 1 and 8 the greatest relief appeared after the third injection gives rise to interesting biochemical speculation.

CONCLUSIONS

1. Expectant treatment of epidemic encephalitis is frequently unsatisfactory.

2. At the same time no other treatment has been found to be more available and useful.

3. The blood serum of patients suffering from encephalitis has been used intraspinously thirty-nine times in this series without untoward result.

4. The cases in which it has been used have been for the most part of very long standing and, therefore, likely to have had definite destruction of tissue.

5. In five out of seven cases temporary but definite improvement has followed these injections.

6. These results may be due either to the irritating effect of the injections, or the blood serum may contain therapeutic properties not present in cerebrospinal fluid.

7. Theoretically there should be a time when such treatment would be particularly helpful. This period is probably after the acute onset and before the symptomatology has settled into an unvarying syndrome.

8. *The results in this series of cases, and especially in Case No. 8—Parkinson's disease—suggest that symptoms in chronic central nervous disease usually looked upon as permanent may not be so. They may be due to the overwhelming and consequent paralysis of nerve tissue by toxic substances. Early relief of such irritation may result in recovery.*

THE OLD CHESTNUT OF THE CHINESE THEORY OF MEDICAL PRACTICE APPLIED

The World's Work, September, 1922, in an editorial states: "It used to be the custom of popular writers on health and medical topics to begin their articles with a reference to the Chinese system of medical practice. According to this the Chinese paid their doctors not for curing them but for keeping them well, and, like many of the ideas of the inscrutable Oriental, this conception is sound philosophy. This is shown by the fact that it is rapidly being incorporated in American medical practice, for it is the idea which forms the basis of modern conceptions of preventive medicine. More and more medical practice is being influenced by the belief that it is the chief business of the profession to prevent disease and that its mere curative activities are of minor importance."

Quite a number of writers in the public press are emphasizing the increased importance of preventing disease and are considering the treatment of disease of "minor importance." Statements of this character are amazing, because anyone who cares to take the trouble to investigate finds that never in the history of the world was there more sickness than there is today. The number of physicians are increasing, the number of hospitals are rapidly increasing, the agencies of medicine are being multiplied, and still one of the principal legitimate criticisms is, that competent medical facilities are not available to all of the people.

Articles of the character of this editorial are, of course, essentially propaganda for that school of "advanced thought" who are trying to deprecate the "doctor of medicine" and to substitute for him the new revised and up-to-date "sanitarian."

With some thirty million people ill this year in the United States, with a hundred and twenty thousand sick every day in California, the services of good, conscientious physicians who understand pathology and whose treatment of illness is based upon education and experience, were never more needed than they are now. It is a fact that every one of the six thousand physicians in California also is doing all that he can do to prevent illness. He has been educated to discharge this duty as he has that of treating disease, and he will continue to be the family and community health officer in the hearts of the people of this State long after the "sanitarian" has perished with waiting for the promised millennium that is not yet in sight.

TRAUMATIC DISLOCATION OF BOTH TESTICLES

REPORT OF CASE

By C. LEWIS GAULDEN, M. D., Los Angeles

A very careful search of medical literature shows this condition to be so extremely rare as to warrant a report of this case. I can only find five cases reported of complete dislocation of the testes.

CASE REPORTS

History—J. E. W., white, age 32, married and the father of three healthy children. Denies all venereal diseases. Passed U. S. Army examination and also employee's examination as given by Southern Pacific Railroad Company. He is sure that both testicles were in their normal place in scrotum prior to accident to be subsequently described.

While at work as brakeman on a log train, logs became loosened in some way and patient was thrown from car and pinned between two logs, compressing his abdomen, also both bones of his right leg were broken at its lower third.

Examination—On admission to hospital two hours after accident, I found patient very much shocked with pulse weak and thready and in rate from 130 to 140. Temperature sub-normal, and systolic pressure 90. Patient had vomited once. He complained only of pain in groins and scrotum and exclaimed, "I have ruptured myself."

Patient's face had rather a pinched expression, abdominal muscles were held rigid. Masses could be felt on both sides in regions of inguinal canals that were very sensitive to touch. Scrotum about the size of an ordinary baseball, soft in consistency and very much discolored; however there were no external marks of injury to scrotum. The testicles were both absent from scrotum, and in fact nothing could be felt in scrotum except apparent blood clot.

Both testicles were found in inguinal regions. Patient was put to bed and treated for shock and expectantly. By manipulation of right testicle by both patient and myself, we were able on third day after accident to replace testicle in scrotum.

The left testicle, however, we could not move and eight days following accident under ether anesthesia I operated on left side. The usual hernia incision was made and the testicle was found beneath the skin and superficial fascia on top of external oblique aponeurosis. Veins of the cord were lacerated and thrombosed. The testicle lay about 1½ inches above the external ring. There was no visible damage to epididymis or vas.

The testicle was replaced into scrotum and patient made uneventful recovery and resumed his position as a railway brakeman.

Standardization—Why is it that the same men who detest socialism will accept standardization in principle and practice? If standardization means anything it means a soft pedaling upon individualism. From either a philosophic or a practical standpoint there is no essential difference to be distinguished between the principles of economic and political standardization and those of scientific standardization. In the one case you are supposed to create a sample citizen who will function, cog-like, with exactly similar fellow citizens, within very definite, prescribed limits, and who, in return for his stereotyped service, will be insured against idleness, ignorance and penury by the State. In the other case you are supposed to create a sample surgeon, an automaton who can be depended upon to function competently, just like all his fellow surgeons, within prescribed limits, and who will be insured against distinguished achievements by the American College of Surgeons.

All these gentry ought to embrace socialism naturally and affectionately.—The Medical Times, October, 1922.

FOREIGN BODIES IN UPPER AIR AND FOOD PASSAGES *

A CLINICAL REPORT

By HARRINGTON B. GRAHAM, M. D., San Francisco

What Jackson said in 1915 concerning the armamentarium in bronchoscopic or oesophagoscopic work is still pertinent, in spite of the advances made in the mechanics in this field. He then said that there was no one set of instruments which could be considered the best for all work or for all men: that it was more the man behind the instruments that was going to save life rather than the instrument itself. If one has at his disposal the large tubes of Mosher, as well as the small ones of Jackson and has practiced with both, he will certainly choose the Mosher tubes for the examination of an oesophageal carcinoma in an adult, and the Jackson tubes for a foreign body in the bronchus of an infant.

The advantages of a proximally lighted tube for diagnostic purposes are, it seems to me, beyond a doubt but the disadvantage in the dispersion of light from an instrument introduced into this tube during the removal of a foreign body tends to render it far less serviceable than the distally lighted tube. Skill in the handling of any of the instruments can only come with painstaking practice, and the best results will certainly follow through a skill acquired in the use of a variety of instruments. Our ultimate purpose is to save life with the least damage to the tissues involved, and with the least strain on the patient; not to satisfy our egotism by a claim that a foreign body has been removed with the smallest tube in the shortest time on record. If by using a small tube the patient is subjected to three seances, whereas had a larger tube been used it could have been removed in one, it were better to have chosen the larger diameter tube. Each case must be judged by itself, and that method or instrument selected which will best fit the circumstances and conform to the skill of the operator.

In analyzing my cases I have been surprised at the large number of unorthodox methods used, and still out of forty-three cases of foreign bodies there has been but one death, a mortality of 2.3 per cent or 5.8 per cent of the bronchoscopies. For instance, in two cases (Nos. 1 and 32), I resorted to a low tracheotomy in order to reach the foreign body; in both cases a prolonged effort had been made to get the article, and in each case it was readily extracted through a tracheotomy opening. Again, a fluoroscopic bronchoscopy was done twice, once unsuccessfully and once with a most satisfactory result. The successful case (No. 33) had been tried under local anaesthesia a year before, but there was such a large quantity of pus present that there was but little chance of locating the article, a shirt stud, by vision. Under ether, with the fluoroscope a tube was passed readily to the article, and later a forceps, which was closed upon the stud and a successful result obtained. The stud had been in the left lower lobe for twenty-three years, and granulation tissue had formed over it. No effort was made to remove the granu-

* Read before the San Francisco County Medical Society.

lations as Jackson had done in a similar case, as the probe passed so easily. At no time was the foreign body seen through the bronchoscope, but the forceps seemed to enter a cavity when passed to it, and there seemed to be little chance of grasping lung tissue.

Unorthodox methods do not necessarily mean poor judgment. They may mean a less skilfull technic, but perhaps a more rational safety for the patient. I have seen a little patient go back to bed in shock after a struggle with the overzealous staff of physicians who were attempting to pass a tube without an anaesthetic, whereas a little ether would have quieted the nerves of both the physicians and bystanders, to say nothing of the patient. It is one of the triumphs of surgery that this can be done so easily by the skilled endoscopist. It is one of the tragedies that it should be tried by the less skilled in a well-intentioned but ill-advised effort to save the child or show his prowess.

There have been foreign bodies which, if dislodged, would close off the only lung tissue which was functioning where it was extremely desirable to operate without an anaesthetic, but these cases are few and far between, and I believe that, with the bronchoscope in such universal use as at present, that it would be far wiser to advise the use of an anaesthetic until the requisite skill had been acquired. After the tube has once been introduced, we all have found that it takes but little ether to continue the work indefinitely, especially if cocain is used at the distal end of the tube. All of my cases under six years of age save one, two cases of the five between six and twenty years of age, and two of the twenty-five above twenty years of age were etherized. All of the others were cocainized, save a baby of eight months on whom an oesophagoscope was passed. For diagnostic or treatment purposes, strictures, carcinoma, thyroid, asthma, a number of cases have been examined without an anaesthetic, but with indifferent success.

In the diagnoses of these cases some interesting facts were brought out. In five cases (2, 21, 27, 32, 38; metal whistle, gold crown, primer, pine-nut, blanched almond) a whistling could be heard, in three near the patient and in two across the room; in each case it had been observed by the family before seeking the doctor. This whistle immediately disappeared on removal of the foreign body. It has been the solid bodies which nearly occlude the main bronchus, which apparently produce this whistling sound.

In Case 3 the patient insisted for years that he had a tack in his lung, but was laughed at by his doctors. It remained in twenty years, causing hemoptosis, night sweats, pus expectoration, and fever.

Case 33 was accepted in the army after an extensive lung examination, including a radiological examination on account of the claim of the patient. After entering the army, further X-ray pictures were taken with a negative result. After discharge from the army, at which time he says he was declared to have had normal lungs, he developed a lung abscess and fell into my hands. A radiograph showed clearly the metal shirt-stud in the left lower lobe bronchus of about the fourth degree.

In Case 32 the radiograph showed an uneven edge at the top of the primer, which should have been interpreted as a closure of the top. The error in not so interpreting it cost the child a number of seances. Too much emphasis cannot be laid upon a prolonged and careful study of every element connected with the diagnosis of the character, size, shape, and location of the intruder before any attempt is made whatever at removal, for at times the simplest element may be the secret that effects the solution of the problem. A hurried diagnosis and an eagerness to get at the case has been the only cause, I believe, of many a failure. The mere presence of a foreign body is seldom a tragedy, but a failure to get it at the first sitting may be.

A diagnostic symptom, which has been held of value in these cases, is a sudden spasmodic cough in a child which has been previously well, but this sign pronounced in its suddenness was present in a child of two years in whom no foreign body was found, and who passed through a typical attack of lobar pneumonia, so that one cannot rely entirely on such a history.

Special points of interest noted in the treatment of this series of cases are:

Case 17—A gold clasp-pin, lying open in the left bronchus of a nine-months-old child, was so manipulated as to bring the point of the pin into the tube, the body of the pin was then grasped and pulled through the tube. For two days there was a temperature of 101-103, and considerable difficulty in breathing, relieved by a steam tent. Subsequently, the child made an uneventful recovery.

Case 18—A case of an open safety pin in the upper third of the oesophagus of an eight-months-old child. Again, the point of the pin was brought into the lumen of the tube, the body of the pin grasped and the pin partially closed, the tube and pin being brought out together.

Case 23—The open safety pin was at the lower end of the oesophagus in an eight-months-old child. I had no pin-closer which would pass through the tube, and as the surroundings were unfavorable, I judged there would be more trauma in an attempt to extract perorally than there would by an incision through the abdominal wall. I, therefore, passed the oesophagoscope after an incision had been made and pushed the pin down onto the finger of the surgeon. The whole operation took twenty minutes, and the child made an uneventful recovery.

Case 22—Was that of a bullet in the antrum. The surgeon, while operating under ether with a fluoroscope, lost the lead, which dropped into the right bronchus. I was called to the hospital, and introduced the tube while the patient was still under the ether. It was a strange and fortunate coincidence that where a fluoroscope was so necessary it was being used for another purpose.

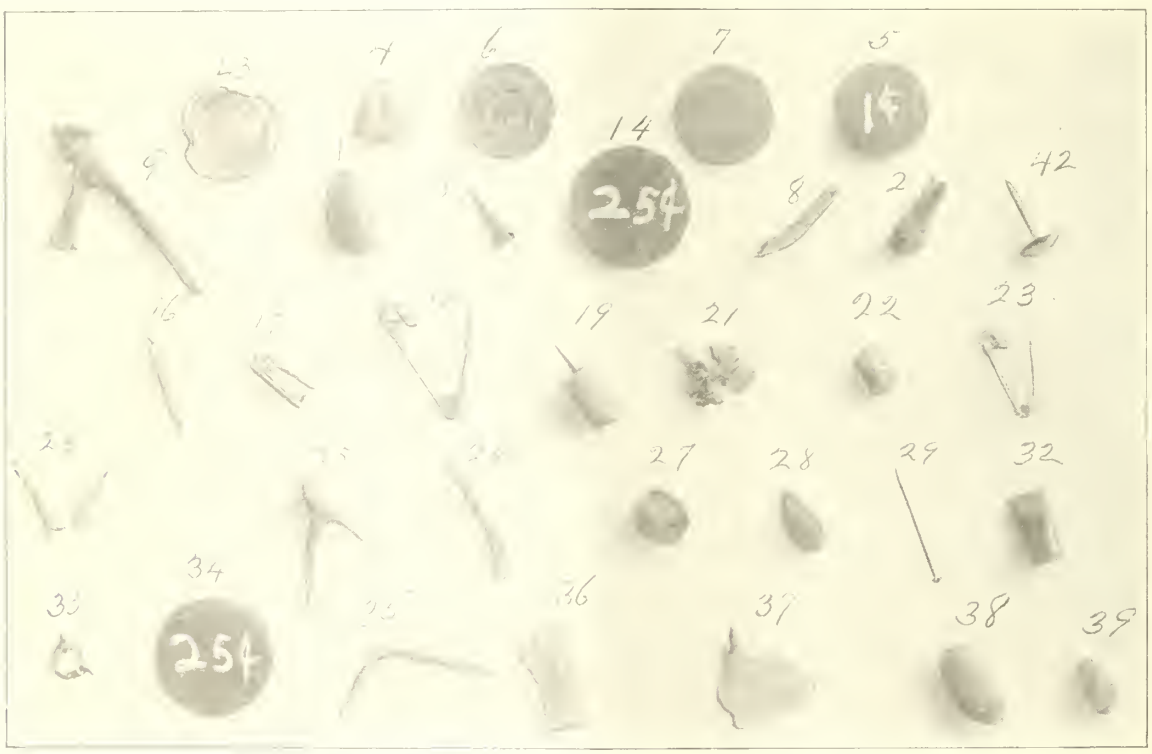
Case 24—Was a series of tragedies. The patient, an adult, had swallowed a chicken bone, which had lodged in the upper portion of the oesophagus, and after three days produced an abscess in the neck. The bone was removed under local anaesthesia, but in so doing a porcelain tip of an incisor tooth was broken off and slipped outside of the tube into the abscess cavity. Three unsuccessful efforts were made to reach it perorally, during one of which the tip of one of the forceps broke off, lodging in the oesophagus and necessitating its removal. An effort was now made to reach the porcelain through an incision in the neck. At no time were we able to feel the article, but the manipulation evidently forced it into the oesophagus as an X-ray subsequent to our operation showed an absence of the porcelain. An ill wind seemed to be following this patient, as while I was working on her, her mother aspirated a small fruit pit and was about to submit to a bronchoscopy when, after three days, she coughed it up.

Case 25—Was a wish-bone, which had been pushed into the larynx by digital manipulation, lodging in the sinuses of Morgagni in such a way as to be nearly invisible to the mirror. It was extracted by the indirect method, causing a sensation of astonishment to the operator as it gradually unfolded itself; part of the bone was broken off after extraction, so it does not show in toto in the illustration.

Case 27—A gold crown was found in the left bronchus of an adult, with the open portion up so that it was easily grasped. It would not pass through the tube, however, and caught at the glottis; an effort was made to manipulate it through the glottis, during which it slipped off the forceps, dropping, fortunately, into the oesophagus, and was promptly swallowed.

Case 32—A child of four years, with a 22 primer in the right bronchus, had four bronchoscopies (three by myself) without the operators seeing the foreign body. The only explanation I can give is that the primer was lying close to the lower wall, and fitted so snugly that it appeared to be the carena itself. Through a low tracheotomy and a large tube there was no difficulty about locating and removing it.

Case 39—Had been shot in the face fifteen years before, and had not known that he carried the lead about with him. He came to me complaining of a soreness in the posterior pharyngeal wall, and an X-ray revealed three pieces of lead, one of which was ulcerating through. This one was easily removed, but the other two were not located, even under ether.



Case 40—While driving a machine on the highway, a man suddenly was cognizant of a stinging sensation in the throat and an inability to talk. On examination it was found there was blood on the skin over the larynx, and he was taken to the hospital. An X-ray revealed a .22 bullet imbedded in the larynx wall, evidently a chance spent shot. A surgeon made an unsuccessful attempt to remove it through an external incision, when I was permitted to see the case. To date the body remains in situ. An unsuccessful bronchoscopy was done by another surgeon in an effort to get the article.

Case 41—A child of fifteen months had inspired a tack, which had lodged in the right bronchus, and the X-ray showed it at the level of the diaphragm posteriorly. A bronchoscopy did not re-

veal the tack, and the child developed a pneumonia, from which she died five days later.

Case 42—A twelve-year-old boy came to the hospital eight days after having swallowed a furniture tack. One attempt had been made to get it, but unsuccessfully. X-ray revealed the tack in the left lower lobe bronchus. There was a temperature of 104 with remission to nearly normal each day and signs of pneumonia, leucocytes of 26,000, so that there was a delay of five days before a bronchoscopy was attempted. As the temperature did not go down, a successful attempt was made to extract the tack, the temperature immediately dropping to normal and remaining there.

The first fourteen of these cases were reported in the California State Journal of Medicine, September, 1916.

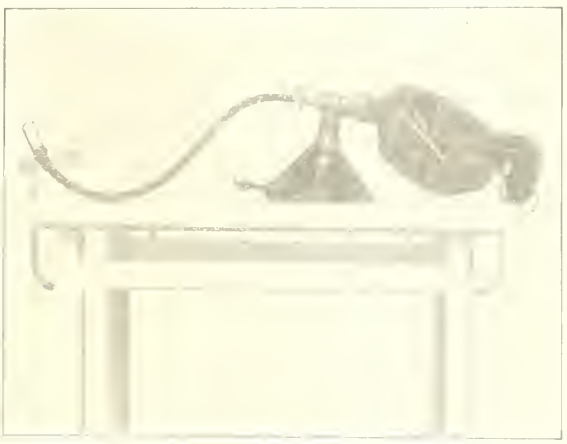
PRELIMINARY REPORT ON ETHYL CHLORIDE ANESTHESIA IN MINOR OPERATIONS *

By LOUISE A. OLDENBOURG, M. D., Berkeley

Ethyl chloride (aethylis chloridum) is a colorless, extremely volatile liquid, with aromatic odor and sweetish taste. It boils at 12.5 C. (55 degrees F.), and so must be kept in sealed containers. The anesthetizing power of ethyl chloride was reported by Flourens in 1841, and the drug was first administered as a general anesthetic by Heyfelder in 1848. As an anesthetic it may be administered by either the open or the closed method.

The cases here reported were anesthetized by the closed method, with Daniell's mask. They comprise observations in operations of less than ten minutes' duration. When this method is employed after three or four respirations, the breathing becomes deeper and more rapid, remaining regular, deepening to a slight stertor, face flushes to a healthy red, slight perspiration may appear on the face and neck, eyeballs move from side to side,



The Daniell's Mask Used in the Administration of the Ethyl Chloride Anesthesias.

becoming fixed in a convergent squint, usually downward. Pupils are dilated and the corneal reflex is lost. The pulse is full, regular, and slow. To avoid crowding or a sudden concentrated flow of vapor, the tube containing the ethyl chloride was gradually immersed in hot water. Observations were based upon eighty-five cases of tonsillectomy and adenectomy (by the Sluder method) in patients from two to fifteen years of age, and twenty teeth extractions (some requiring gouging of roots) in patients from six to fifty-six years of age. The time of induction of anesthesia was from 30 to 60 seconds and the time from the beginning of anesthesia, completion of the operation for removal of tonsils and adenoids to the return of consciousness was from four to five minutes. The average anesthesia was smooth, without a stage of excitement or agitation, and with complete muscular relaxation. Upon recovery, in several patients, there was stiffening of the extremities and delirium, some vomiting, but no masseter spasm nor respiratory paralysis. The closest approach to this type occurred in a girl nine years of age, taking 3 cc., who held her breath for a few seconds, had twitching of eyelids, and stiffening of the extremities; but she had a quiet recovery without nausea or vomiting. A very nervous woman (forty-five years) anesthetized for the removal of a vaginal pessary, and who took 4 cc. of ethyl chloride, had clonic contractions of the extremities, with very *slow,* full pulse and retarded but satisfactory recovery. A three-year-old boy came to the operating-table with a nickle in his hand. Upon awakening, still on the operating-table, and being shown the coin, he recognized and reached for it. Children of two to three and four years of age were carried to the recovery room, the rest walked to their beds. If the throat required inspection after the operation, the little patients always responded to orders and opened their mouths. A stage of analgesia continues for some time afterwards, permitting further manipulations if necessary.

To procure success in the administration of ethyl chloride the drug must be chemically pure, the dose must be properly regulated to suit each individual case, and care must be exercised owing to the rapid transit of the drug from the second, to the third and fourth stages. Rather than to increase the amount of 5 cc. of ethyl chloride for an adult, it is advisable to add 1 cc. of ether, thereby prolonging the anesthesia without increasing the dangers. However, the dose should not be a hard-and-fast rule. The weight, height, build, and general appearance and condition of the individual should be considered and be the guiding factors. Recently, as you all know, the safety of ether and particularly chloroform, has been increased by the addition of oxygen. Gwathmey and Rice are advocators of this addition to ethyl chloride. The description of ethyl chloride anesthesia of Hewitt more or less coincides with the later work of Guedel which condition he designates *spasm type* and the *depression type.* Contrary to Hewitt, however, who states that ethyl chloride produces a fall in blood pressure and a slow pulse, Guedel claims a loss in systolic blood pressure of only 4 mm. and a loss in diastolic of 7 mm. and an *increase* in pulse rate of eleven beats per minute.

The advantages of this anesthetic are the following:

1. A quick narcosis from which the patient recovers promptly.
2. Ethyl chloride has a pleasant odor and is not irritating to the respiratory mucous membrane.
3. Stage of excitement, if any, is very short.
4. No increase in saliva and bronchial secretions, no cyanosis or venous congestion.
5. The small amount of the drug necessary.

* Presented to the Pacific Coast Association of Anesthetists, May 16, 1922.

6. Readily administered in emergency surgery on account of its portability and where nitrous oxide oxygen apparatus is not available.
7. Vomiting occurs in only a small percentage of cases after anesthesia, and when it does occur, is not prolonged or distressing.
8. It is particularly adaptable to children.
9. May be used for induction to other anesthetics.
10. In *simple* overdose, resuscitation by the usual methods is quickly accomplished owing to the extreme volatility of the drug and its rapid elimination.

The danger signals of ethyl chloride anesthesia appear without warning on account of its quickness in effect and rapid transit into its different stages.

Contra-indications, as follows:

1. It is not suitable for prolonged administration on account of its dangers, expense, and great strain on the anesthetist.
2. It should not be used in alcoholists and neurotics, and is decidedly contra-indicated in mechanical and inflammatory respiratory obstruction; in cardio-vascular degenerations and all conditions giving rise to marked dyspnoea.

Although in 1880 the British Medical Association condemned the use of ethyl chloride as being too dangerous, its use now in England and Scotland is prevalent. In a report of anesthetics given in the Ear, Nose and Throat Department of the Royal Infirmary of Edinburgh, Scotland, for the year 1920, there were over 1200 ethyl chloride anesthesias. This represents double the number of any other anesthetic given in this department. Enthusiastic advocates of this anesthetic are M. W. Ware of New York, A. H. Miller of Rhode Island, Erdman of Brooklyn. Murray, in 1905, reported 150 administrations in infants one year of age; the youngest patients were five to fourteen days old; the larger proportion were from five to seven weeks old. A. H. Miller of Providence, Rhode Island, in 1912, compiled the experiences of twelve anesthetists; in this series there occurred one death in every 13,365 administrations. M. W. Ware of New York, in 1917, reported one death in every 15,000 ethyl chloride anesthesias. In January, 1922, Webster of Winnepeg, Canada, reported 22,000 administrations without a fatality, although the greater number of these were inductions to ether. However, he considers nitrous oxide safer. He uses the closed method, using the Ormsby inhaler and prefers it to the open method. Guedel of Indianapolis uses the Yankauer mask, and places ethyl chloride third in value to nitrous oxide and oxygen and ether, and above chloroform. He reports two thousand cases without a death, fifteen of which were for prolonged anesthesia of fifty-three minutes duration.

(I am greatly indebted to Dr. May Walker of Oakland for her guidance and instructions in my first administrations of ethyl chloride as a general anesthetic in minor surgery.)

INDICATIONS FOR THE ADMINISTRATION OF QUINIDIN IN AURICULAR FIBRILLATION *

By ALBION WALTER HEWLETT, M. D., San Francisco
(From the Department of Medicine, Stanford University.)

In 1918, W. Frey announced that a certain proportion of patients suffering from auricular fibrillation regained a regular heart rhythm after having been treated with quinidin sulphate. This announcement was followed by confirmatory reports from many sources. A review of these reports indicates that certain facts concerning the action of quinidin now seem established. In some patients with auricular fibrillation the drug is clearly indicated, in others its use is not so promising, and in still others it occasionally does positive harm.

The main facts upon which the indications for quinidin rest are as follows:

1. A normal rhythm has been restored in over 50 per cent of the reported cases of auricular fibrillation that have been treated with quinidin.

2. The results obtained have been markedly influenced by the duration of the fibrillation. Where the irregularity had been of very recent onset, the drug usually succeeded; where the irregularity had lasted more than a year, successes were much less common. Of nineteen chronic cases reported by Frey, five became regular. My own experience has been much less favorable; for I have had only two successes where the abnormal rhythm had presumably lasted continuously for a year or more (see Chart 1).

3. Other factors, which apparently influenced the results of quinidin treatment, were cardiac decompensation, cardiac dilatation, and the dose of the drug employed. Cardiac decompensation and cardiac dilatation are said to lessen the chances for recovery of the normal rhythm. Where the normal rhythm has been restored, this has usually occurred with moderate doses of the drug given for two to four days; but in some patients the normal rhythm has become established only after large doses have been given or the treatment has been continued for a week or more. Thus, the percentage of restorations has been somewhat higher when large doses have been given to stubborn cases for a week or more. Neither the patient's age, nor his blood pressure, nor the presence or absence of chronic endocarditis has appeared to influence the results obtained.

4. In the vast majority of patients whose normal rhythms have been restored, the fibrillation has recurred; frequently within a few days, in other cases only after months. Except in paroxysmal types of fibrillation, the persistence of a normal rhythm for nine months or over has been exceptional. Recurrences have frequently been controlled by repeating the treatment; but in some cases the drug, though at first successful, has failed on the second or third recurrence. An important question, not yet decided, is whether such patients should receive the drug continuously with the hope of averting fresh attacks of fibrillation.

5. In most patients, the drug has produced no

* Read before the Section on Medicine of the Medical Society of California, at Yosemite, May 15, 1922.

serious effects. Palpitation and an increased ventricular rate need cause no apprehension, provided the patient's general condition remains satisfactory. Occasionally, compensation has been distinctly impaired by the drug, or syncope has occurred. In a very few cases, death has occurred while quinidin was being given or shortly after it had been discontinued. We are not certain that the drug was responsible for these deaths. It has been suggested that auricular clots may have become loosened by the return of auricular contractions, thus causing emboli. Possibly, also, an impaired compensation or some change in the ventricular rhythm may have contributed to a fatal issue.

6. More or less clinical improvement has usually followed the restoration of a normal rhythm. The subjective discomfort caused by the arrhythmia has usually been lessened. In many cases compensation has been improved; and occasionally it has been practically restored, even where the usual treatment with digitalis had failed.

Bearing the foregoing considerations in mind, we may attempt to formulate the indications for administering quinidin to patients with auricular fibrillation. In every case the possible dangers must be weighed against the probable chances for restoring a regular rhythm, for maintaining this rhythm and for improving the degree of compensation. Furthermore, the treatment itself must be so conducted as to avoid, so far as possible, dangers and accidents.

Beyond doubt, the patients most suitable for treatment with quinidin are those in whom the fibrillation has developed recently and whose hearts have previously been in good compensation. When fibrillation occurs, such patients commonly complain of palpitation, precordial oppression and breathlessness on exertion. If a normal rhythm is not restored after a few days' treatment with rest and sedatives, such patients should always, in my judgment, receive the quinidin treatment. Small doses of the drug usually restore the normal rhythm, and the danger from emboli and other accidents appears to me to be negligible. When the regular rhythm has been re-established, the symptoms usually disappear completely. Finally, in these patients, the heart may remain regular for an indefinite time. After the heart has become regular, such patients should be carefully investigated, in order that focal infections or other causes of cardiac irritation may be determined and removed. It appears to me important that general practitioners should recognize the onset of fibrillation in these patients in order that prompt treatment with quinidin may be given. A failure to do so permits the fibrillation to become more firmly established, so that it is more resistant to treatment. Furthermore, the irregularity itself places a strain on the heart muscle, and in time favors dilatation, hypertrophy, and decompensation.

Where the fibrillation has recently developed in patients with advanced decompensation, quinidin

has restored the normal rhythm in a considerable proportion of cases. Yet, in my experience, these patients are much less favorable subjects for the treatment than are those in whom compensation had previously been good. Often the restoration of a regular rhythm has caused but little change in the patient's general condition and early relapses have been frequent. In these patients, also, the possible dangers from dislodging auricular thrombi, from decompensation and from changes in the ventricular rhythm must be taken into consideration. Despite these objections, I believe that the drug should be given to such patients, unless decompensation is extreme. If a normal rhythm is restored and the auricular fibrillation later recurs, further action must be guided by the effect which one may say in a general way that patients with marked decompensation, greatly enlarged hearts, or evidence of coronary diseases are relatively unfavorable subjects. In chronic fibrillation, then, quinidin has been, on the whole, rather disappointing as a therapeutic measure; yet the occasional brilliant success raises the hope that better results will be obtained when more is known of the drug and of the type of chronic case most suitable for treatment.

In giving quinidin, certain general precautions should be observed. The patient should be kept in bed, preferably under the supervision of a nurse. If there has been cardiac decompensation, this should be improved by a preliminary rest. Some authors recommend that digitalis be not given with the quinidin. One should begin the

the change of rhythm had upon the patient's general condition.

The longer fibrillation has lasted, the poorer, on the average, are the chances for recovering a normal rhythm when quinidin is given. Nevertheless, some patients recover the normal rhythm, even though fibrillation has persisted for months or years, and occasionally a brilliant clinical result has been obtained where other treatment has practically failed. In general, however, the large number of failures in these chronic cases and the marked tendency to early recurrence among the successes, causes one to hesitate about using a drug that appears to be not entirely free of danger. At present, unfortunately, we have no certain method for selecting patients in this group who are most apt to be benefited by the drug; although quinidin sulphate administration with a small dose of three grains on the first day, and then rapidly increase to a maximum of from eighteen to thirty grains daily. If no unfavorable symptoms supervene, the latter should be continued for about a week. Should the rhythm become regular, the drug is best stopped altogether. If the irregularity recurs, and if the clinical improvement during the period of regular heart action has warranted further trial, then the drug should be given again, and if the pulse again becomes regular, the quinidin may be continued in small doses with the hope that it may prevent further relapses.

Unfortunately, we have no certain means of predicting what patients may do badly while taking the drug, and alarming symptoms have occurred, without warning, even after small doses.

For this reason it is necessary to proceed carefully in every case.

CONCLUSIONS

1. When auricular fibrillation occurs in a heart that has previously been in good compensation, quinidin should always be given; provided several days' treatment with rest and sedatives has failed to restore a normal rhythm.

2. When auricular fibrillation occurs in a heart already decompensated, quinidin should be given a trial, provided the decompensation is not very serious. The results in this group of patients are not very satisfactory; not so much because the drug fails to restore the regular rhythm, but because relapses are common and the general condition may not be altered materially by the change in rhythm.

3. When fibrillation has persisted for over a year, the results of quinidin treatment are not particularly encouraging. The proportion of patients who recover a normal rhythm is not great, and many of these relapse after a short time. Furthermore, the dangers from the drug are probably greater in these patients.

4. Nevertheless, occasional patients with long standing auricular fibrillation have shown a remarkable improvement after receiving quinidin, even when other forms of treatment have been relatively ineffective. At present we are not able to predict what cases will thus be favorably affected.

Clinics or Dispensaries and Free Medicine—The report of the Council on Medical Education and Hositals of the A. M. A. (Journal A. M. A., August 5) on clinics and dispensaries furnishes some important data and indicates some rather startling tendencies in medicine. It is apparently conservatively estimated that some eight million persons or about 7 per cent of the entire population of the United States made over twenty-nine million visits to dispensaries during last year. Some of the main facts brought out by the Council in this difficult survey are:

1. There is a steady increase in the number of patients seeking treatment in general dispensaries.
2. There has been an unprecedented increase since the war in the number of special clinics and dispensaries, such as those for tuberculosis, venereal disease, mental hygiene and child hygiene.
3. There is great need for individualized study and treatment of dispensary patients, to counteract what seems to be a prevailing tendency to routinization.
4. There is need of a closer bond between the out-patient service and the other service of hospitals, and this will best be met by having the hospital and the out-patient staffs identical and by keeping unified records.
5. In the matter of finances there is an increasing tendency to charge nominal fees, thereby placing part of the cost of an institution on the patient.
6. A general increase is noted in the use of social service workers to see that patients continue their treatment, and to investigate their social and financial status so as to prevent pauperizing.
7. The difficulty of securing satisfactory data is increased by the inadequacy of clinical and office record systems in a large number of institutions.
8. There is a great and increasing amount of educational work, especially the teachings of interns, medical students, graduates, and pupil nurses.

UNDERLYING PRINCIPLES OF PLASTIC SURGERY*

By JOSEPH A. PETTIT, M. D., Portland, Oregon

The underlying principles of plastic surgery vary with the region of the body in which the procedure is being carried out, and also in reference to the tissues that are being handled. There are certain general principles, however, which apply in varying degrees to all plastic surgical procedures. Certain basic principles are more or less essential to a successful technique in the reconstruction work of any part of the body. In dealing with these principles they may be classified under certain general headings.

1. *Blood Supply:* In the reconstruction of parts, and in securing flaps to fill in defects, great care should be exercised to conserve the blood supply of the transposed tissues. In the selection of the flaps of tissue to be utilized in plastic work two thoughts should be foremost in mind. First, to secure a flap of tissue which is adequate not only to fill in the defect, but to provide for loss of size by a certain amount of contraction; and, second, the flap of tissue selected must have a base that carries blood supply to all parts of the flap adequate for the preservation of its existence. If the base of the flap can be left in that direction from which the nutrient blood vessels naturally come, the security of its integrity is greatly enhanced. That is to say, providing the pedicle of the flap can be so placed as to carry the largest blood vessel which goes to the particular tissue to be transposed, greater assurance is provided for a maximum nutrition than if the pedicle is located where some of the smaller nutrient vessels enter. The base of the flap should be as broad, if not broader, than the greatest width of the flap. If the pedicle can be so located as to carry a large nutrient vessel, the base of the flap can, with safety, be made of less breadth than the transposed flap. Undue torsion of the base of the flap is apt to produce a partial constriction of the lumen of the nourishing vessels and thereby endanger the life of the flap. Undue tension on the pedicle may produce a similar unfortunate result.

2. *Coaptation:* In the placing of plastic flaps, minute attention to the details of accurate coaptation is of considerable importance. The recognized principle of the accurate apposition of the fractured ends of bones to secure solid union applies to plastic flaps as well. In order to secure a good, an expeditious, and a lasting union of any type of soft tissue, it is important that similar tissues contact, and at the same time contact with precision. Fascia should be sewed to fascia, periosteum to periosteum, mucous membrane to mucous membrane, and skin to skin. The mesoblastic tissues can be overlapped and will adhere firmly in a double layer. In dealing with the epiblastic tissues it is necessary to avoid overlapping and to accurately coaptate the cut edges, The fibrous tissue cells will unite together irre-

* Read before the Section on Surgery of the Medical Society of California at Yosemite National Park, May 15, 1922.

spective of position, but the epiblastic cells will not unite unless brought together at their sides or bases. The sutures used in coaptation of the flap edges must be tight enough to maintain a continuous and perfect contact, and at the same time not so tight as to produce a pressure necrosis, with the resulting local irritation, tendency to infection, and a possible cutting through of the sutures.

3. *Plastic Flaps:* The advantage demonstrated in bone surgery of securing a graft containing all of the bone elements, namely, periosteum, osteum and endosteum, is recognized. The integ-

Fig. 1
Incorrect selection of flaps to preserve vascularity. (Diagrammatic)

rity of plastic flaps is enhanced by applying this same principle. A plastic flap on the soft tissues should, if possible, include all the essential tissues of the part. The plastic flap of the cleft palate should include the periosteum on one side and the mucous membrane on the other side with the intermediate tissues undisturbed. The flaps should be a little larger than the places to be filled, in order to compensate for a certain degree of contraction, as well as to prevent traction upon the coaptation sutures. The base of the flap should be as wide as the greatest breadth of the flap. Whenever possible the base of the flap should also be of greater thickness than the remainder of the flap. An adequate pedicle is the best insurance available for the life of the flap.

4. *Tension:* If any degree of tension is permitted to occur in the placing of a plastic flap one can feel a reasonable assurance of failure. A tension endangers, first, the suture line; second, the blood supply of the flap; and third, its growth in the new situation. Coaptation sutures will invariably cut through by pressure necrosis whenever tension exists. Even a very moderate degree of tension constitutes a positive danger to

Fig. 2
Proper selection of flaps to preserve vascularity. (Diagrammatic)

the integrity of the suture line. Before placing any coaptation sutures on any plastic flap, all tension should be sufficiently relieved so that the plastic flap will not only lie freely in its new situation, but will even nestle up to the edges to which it is to be sutured. Tension endangers the nutrition of the flap in two ways, first, by the stretching of the vessels, and second, by a possible torsion, either one of which makes a constriction of the lumen of the vessels. It is extremely important that the flap be well nourished during the early days of its incorporation in the new situation. At this time the new vessels have not grown into the flap as it lies in its new situation from the tissues to which it is united, and its only source of blood supply is through the vessels in the pedicle. The periphery of the flap will secure new blood supply in its new location much quicker if the local nutrition is very good.

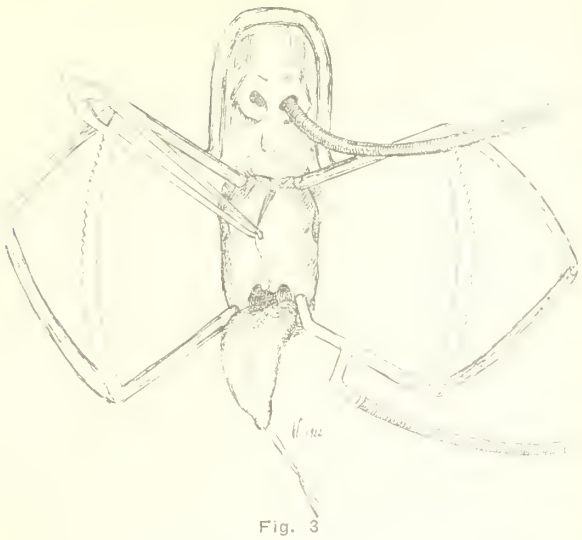

Fig. 3
Adequate loosening of flaps to permit overlapping

The cohesion of the plastic flap in this new situation begins at once. Nature's "cementing" process sets in promptly and gradually becomes firm. If tension exists the flap will slide a little after a few days and this will occasion a loss of all the efforts of the first few days of the "cementing" process, and the whole process will have to be started over again, if it is fortunate enough to start again. Therefore, there occurs an unfortunate delay in the growth of the flap in its new situation, even if it does occur at all.

5. *Immobility:* Plastic surgery receives another lesson from bone surgery in considering the importance of immobility. Providing the dangers resulting from tension are obviated, it is also necessary that no other influence be permitted to disturb the flap during its implantation to the new situation. Immobility may be caused by pressure or traction of other parts. Muscle pull exerts a fatal influence to union. This is especially true in suture of the clefts of the soft palate. The fate of a soft palate suture entrusted to the security of the ordinary coaptation sutures is in constant danger. Every act of swallowing, talking or crying on the part of the child means a contraction of the palatoglossal and palato pharyngeal muscles. Each contraction of these muscles makes a definite and distinct pull on the suture line of the median raphe of the soft palate. This pull means a traction on the coaptation sutures with the resulting danger that they cut through. No soft palate suture may be considered safe without the use of the lateral lead plate splints and silver wire, as shown in the illustrations. The broad surface of the lead plates take up the traction of the muscles and if they are drawn up snugly enough, no motion of the pharynx and tongue will produce any traction upon the coaptation suture line.

6. *Suture Materials:* Horse hair has two distinct advantages. First, elasticity, and second, absence of capillary attraction. During the early stages of any healing process there is a mild congestive swelling of the coaptating tissues. A suture which is non-elastic will produce local irritation. Horse hair has just enough elasticity to compensate for this moderate degree of swelling, and when the swelling disappears will draw down and maintain an accurate coaptation. The absence of this "coaptation traction" eliminates one of the possibilities of infection being carried into the deeper tissues. The pressure necrosis of a cutting suture constitutes a possible local infection focus. If there exists the danger of a slight degree of tension the sutures can be applied as a figure eight suture, giving an accurate coaptation, and at the same time a reinforcement. It is probable that the figure eight suture should be used more often than it is, especially in plastic surgery of the palate.

7. *Time:* The time required for the union of plastic flaps varies. The type of tissue involved in the plastic work as well as its vascularity governs the time required for union. The plastic transplant whose pedicle is to be cut off requires a little more time and consideration than the flap with a pedicle that is permanent. A small flap will gain an adequate circulation somewhat earlier than a large flap. In addition a flap which has a large and thick pedicle carrying a proficient blood supply can be cut loose somewhat sooner. Some tissues are more vascular than others and the length of time required for a solid implantation of the plastic flap is less in tissues which normally have a maximum degree of vascularity. The kind of tissue transplanted also governs the length of time required for permanent implantation in the new situation. As a rule the epiblastic structures unite more rapidly than the mesoblastic. A longer length of time must elapse before entrusting fas-

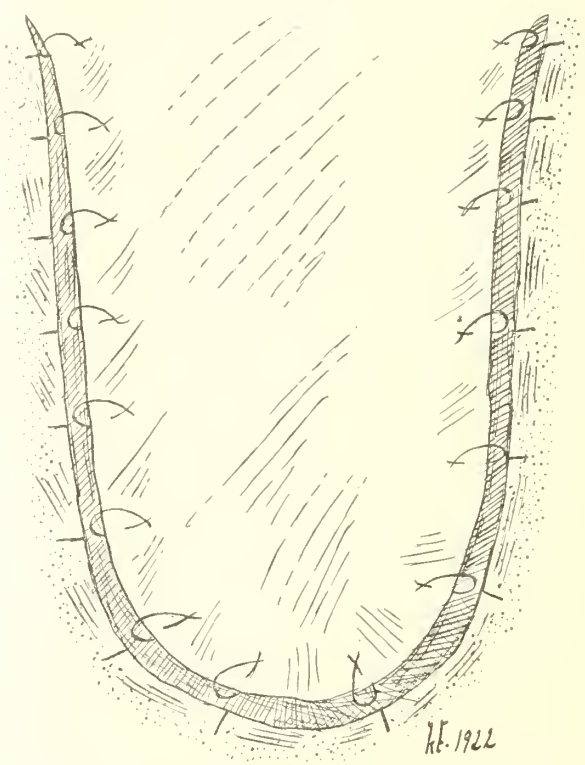

Fig. 4
Stitches may loosen by pressure necrosis when tension exists

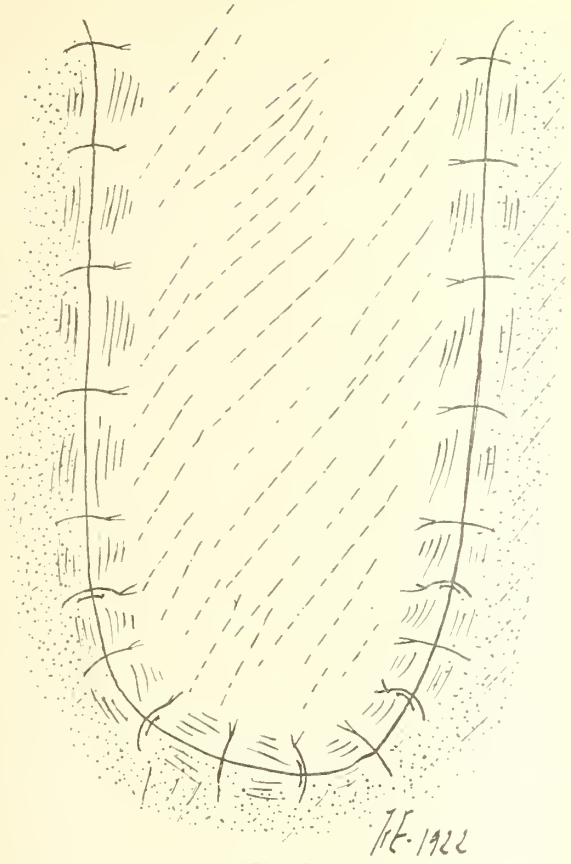

Fig. 5
Undermining adjacent tissues helps to obviate tension on sutures

cial tissues to resume a normal function than mucous membrane. Likewise in osseous plastic work the maximum length of time is required before the new union can be entrusted with any strain. The osteoblasts slowly perform their physiological function in bone repair and union.

8. *Asepsis:* Asepsis should be maximum, considering the environment of the operative field. While plastic work on bones requires surgical technique as immaculate as abdominal work in order to ensure success, plastic work in the oral cavity must be done under conditions that can be rendered only relatively aseptic. In the latter situation we find primary union not difficult to obtain under environments which would prohibit success of an osteoplastic procedure. The bacteriological

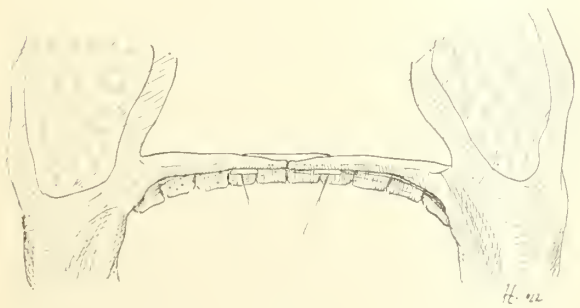

Fig. 6
Muscle pull counteracted and immobility established by lead plate splints

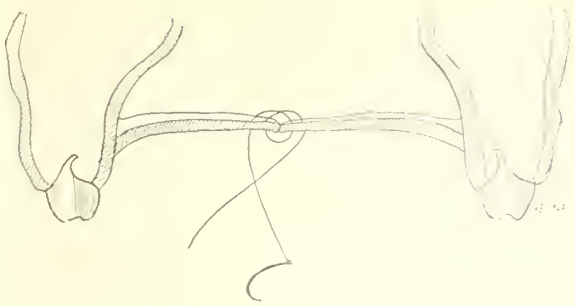

Fig. 7
Figure of eight suture gives both coaptation and retention

explanations of this fact are accepted with credence, if not by proof. It seems important, however, to strive to attain in plastic work the maximum degree of asepsis which is possible under existing environments.

Of Interest to the Thoughtful—As can be testified by the educational committee of the A. M. A. no little trouble has been experienced in making those in control of the Rockefeller Foundation understand the attitude of the medical profession toward medical education and function which medical men should have. Any controversies that have arisen have been due largely to the fact that the Rockefeller Foundation is dominated by a lay element which either cannot or will not consider medical problems in a professional way. Just now the Michigan medical men are up in arms concerning the proposal of the Rockefeller Foundation to establish a separate independent profession no longer subservient to the medical profession. The graduates from this school are to be classed as "super-nurses," and their activities are to be directed along the lines of preventive medicine, health clinics, prenatal clinics and public health work, with, as they state, the home as their field of activity. These activities they will engage in without the aid, advice or direction of doctor or the profession. Such a move would deprive nursing education of its most important contact with those whose years of experience qualify them to care for the sick. It also would deprive them of the training and contact which is absolutely necessary for the best results if the patient, the one most concerned, is to be benefited by the enterprise. As understood by some of the medical men of Michigan, the plan as proposed would have a tendency to make the nurses superior to the physician who is responsible for the treatment of the patient, and the views of the medical profession would have no weight in the training of nurses. It remains to be seen whether the University of Michigan, which has been flirting with various schemes that seem to be antagonistic to the highest type of medical education and practice will "fall" for the plan offered by the Rockefeller Foundation. Perhaps the million-dollar fund which accompanies the offer will have a determining voice in the matter.—Indiana Medical Journal, September 15, 1922.

Reduced Price of Radium—We offer you, for prompt acceptance, radium in tubes at $70 per milligram, delivery within sixty days from date of sale, and payment to be made upon receipt by your bank. The price includes certification by the United States Bureau of Standards, and all neeessary screens and appliances for proper therapeutic use.—Radium Chemical Company, Pittsburg, Pa.

TREATMENT OF ACTIVE LUES *

By HARRY E. ALDERSON, M. D., and
GEORGE H. BECKER, M. D.
(From the Department of Dermatology and Syphilology, Stanford University Medical School, San Francisco)

During the year 1921 we have studied approximately 500 cases of syphilis, which represents about one-third of the total attendance at the skin clinic.

We are comparing the results of various methods of treatment and expect in another year to have sufficient data from which to make instructive comparisons and draw important conclusions as to therepeutics. H. C. Coe recently made a survey of the luetics treated between 1912 and 1918. A similar study of the period from 1918 to 1922 will soon be completed. The first survey showed that less than 12 per cent of the patients remained under treatment and observation for one year or more. Of these only 19 per cent have been apparently cured. Actual cure will be determined only by long years of observation and repeated blood and spinal fluid examinations. These 19 per cent, however, showed negative serological and clinical findings repeatedly *two years* after treatment was suspended—13 per cent of the 12 per cent have remained *Wassermann fast* but *clinically well.* The disorganization of our social service staff as well as the unusual labor conditions incident to the war has interfered somewhat with the completeness of our data. The report of the past four years' work will be much more complete. The difficulties encountered in obtaining the cooperation of the patients is similar to that elsewhere and always interferes with the accuracy and completeness of records.

In this preliminary paper our hope is to stimulate a general discussion of the subject and to emphasize the fact that antiluetic treatment should not and *can not be standardized.* Not only do patients themselves present variable factors, but the treponema pallidum is believed by some to vary in its resistance to the action of drugs.

The treatment of lues *must be individualized*—the best results are expected to follow and almost invariably *do* follow, energetic arsphenamine-mercury treatment administered during the earliest stages of the disease before the Wassermann reaction has become influenced. The intensiveness of our treatment must, of course, be regulated by the condition of the patient, who may present some constitutional disease. Heart and kidney complications always call for a less energetic procedure. The effects of the drugs upon the different viscera must be remembered. The cumulative possibilities and the slowness of elimination, particularly in the late cases, as recent work has shown, should serve as a warning in our anxiety to "push" the treatment. Wile, whose recent paper before the Academy many of you heard, pointed out the danger of producing too rapid involution of visceral lesions, particularly the liver and aorta, by intensive arsphenamine therapy. Others have warned against the danger of small ineffective doses producing arsenic resistant strains of treponemata.

We are carrying out the following general plan, being very careful to individualize in each case so far as is possible.

Every patient upon admission is given a complete physical examination and in addition the routine laboratory tests, such as blood count, Wassermann and urinalysis are made. During the course of treatment the Wassermann and urine tests are repeated at regular intervals and bearing in mind the possibility of early invasion of the cardio-vascular and central nervous systems physical examinations are repeated at frequent intervals.

The drugs used in the treatment of syphilis have been more or less fundamental, with various minor modifications in the manner of administration and some chemical changes. Of the various methods of administering mercury we now prefer the inunctions. Of the arsenicals, arsphenamine is, we believe, still the choice. Upon the introduction of silver salvarsan we ran a small series of cases (fifty injections), but were unable to find any superiority of this article over the older preparations. We now use neoarsphenamine as a substitute for arsphenamine only when necessary and then in average dosage of 0.9 gm. for men and 0.6 gm. for women.

For therapeutic purposes we use the American Dermatological Association's classification of "early" and "late" lues. The former includes those cases showing an initial lesion, positive "dark field" findings with or without a positive Wassermann reaction—also those cases with constitutional manifestations showing that the infection has become generalized. The physical signs and Wassermann in these cases are usually positive. The late cases include those showing clinical or serological evidence of a luetic infection, usually of at least one year's duration. Here the treponemata tend to become localized in various organs and tissues.

The early cases receive arsphenamine-mercury treatment consisting of six intravenous injections of arsphenamine at weekly intervals (men 0.6 gm., and women 0.4 gm.). For the patients who are working, or who for other reasons can not stay in the hospital over night, we use neoarsphenamine, which rarely causes any interference with their occupation. The usual intravenous precautions are practiced and distilled water is used as a diluent, each dose being dissolved in 30 cc. of water. Reactions are practically unknown. Along with the intravenous therapy-mercury is also prescribed—preferably as inunctions in a course of thirty daily rubs (using 4.0 for men and 2.0 for women). A sheet of printed instructions accompanies this prescription explaining in detail the exact method to be followed, favorable sites to be used and the early signs of mercurialism. The use of benzine for cleansing as suggested by Cole removes one of the most disagreeable features connected with rubs, but here we insist very strongly upon the rub being continued for one-half hour or more. The official Unguentum Hydrargyri (50 per cent) is prescribed in flexible capsules. At times, the biniodide of mercury is prescribed in solution (dose gr. 1-15) and rarely produces gastric symptoms. With it, we give the iodides in the usual form in a *separate solution.* Following

* Presented to the San Francisco County Medical Society.

one course of arsphenamine-mercury as above outlined, it is customary to give a rest period of three weeks, after which a blood Wassermann test is made. If negative, another course of mercury is given, while if positive the entire arsphenamine-mercury series is repeated. The late cases also receive six weekly injections of arsphenamine accompanied by mercury, the latter being frequently given in solution as biniodide. Iodides are administered as indicated, the potassium salt being preferred, prescribed as a saturated solution. All cases having a negative blood Wassermann taken at three months, six months, one year and two years, *after thorough and complete* courses of treatment, accompanied by a negative spinal fluid and free of clinical signs are tentatively classed as "cured," but are instructed to report semi-annually for observation. This criterion of a "cure" we have rather arbitrarily adopted and feel that it is perhaps too rigid, but one under which we can conscientiously sanction marriage. Even then, we advocate further medication yearly for several years, depending upon the case and conditions. The provocative Wassermann is too uncertain to be of value, as shown in a recent thesis by Ruth Shepardson of our clinic. The luetin tests also are worthless, as shown by Alderson's work with commercial luetin.

The ideal treatment of syphilis has not yet been found. Some prefer the old salvarsan, some the neoarsphenamine and others the later and newer preparations. Mercury is used as rubs by some and by mouth or by injection by others. Regardless of the individual choice *we do know* that the infection *must be seen early and vigorously and persistently treated with all the means* at our disposal for a prolonged time, if we hope to get a permanent cure. Even then, it will take years to determine a definite cure.

Medicine a Service—Medicine is a profession of service and not a commercial venture; any attempt to make it so will end in discredit and usually failure. True, we must live by our work, but in my life I have never seen the man who works for the joy of it, go hungry or his children begging for bread. It is the law of life that he who gives most gets most, and the men who give most are usually the men who are accomplishing most in every walk of life. I have often thought if the young men in medicine knew the joy of God's open country, more of them would be country doctors.—Kay in American Medical Press, September, 1922.

"Each State hospital owes to its patients complete medical service," says Mr. A. L. Bowen in an article in The Modern Hospital. "A State hospital medical service to be complete must be prepared to give each patient, both on his arrival and at frequent intervals during his stay, every possible advantage that he could get in the very best private general hospital; everything, indeed, that will help to place him in first-class condition physically, and to adjust himself mentally to his environment, so that he may resume within his limitations the pursuit of occupation, recreation, and the pleasures of life. These privileges will render his stay in the institution serviceable to it and to himself."—The Modern Hospital, August, 1922.

THE DIFFERENTIAL PUPILLOSCOPE *

By OTTO BARKAN, M. D., San Francisco

Some ten years ago, during his attempts to determine the absence or presence of color vision in animals, C. Hess devised an instrument which gave a quantitative measure of the sensibility of the pupillary reaction.

In subsequent years the clinical significance of the method became apparent and it was adapted to clinical use. Inasmuch as it gives us a norm for the light reaction of the pupil, is free from all sources of error, is independent of the state of adaptation and age of the individual, it has become of considerable diagnostic aid in clinical medicine as well as in the restricted field of ophthalmology. The method was published two years ago. From my own experience I do not doubt that in the course of the next few years it will become a necessary adjunct to every well-equipped institution and also, even if to a more limited extent, in the dark-room of the specialist.

The underlying principle of the method, though simple in itself, is so unfamiliar to our modes of thought that it is at first not easy of conception. For its detailed description the reader is referred to the original articles. Let it suffice to state that with this instrument we measure the reactivity of the pupil by determining quantitatively the least difference of light intensity which is necessary to produce a reaction. It has been found that physiologically the pupil does not react to a difference of light which is less than 95 to 100. When the difference of light is greater than this the pupil responds with contraction upon appearance of the brighter light. The difference of light intensity necessary to just cause a reaction is thus a measure of the sensibility of the pupillary reaction and therewith of the reflex arc entailed. The importance of the determination of such a norm immediately becomes apparent. It is not influenced by opacities of the media, such as cataract, nor by refractive errors. Nor does the pupillary play interfere in practice with the examination.

The nature and localization of fundus lesions which may affect the reaction have been worked out. Thus it has been found, and this is in harmony with other recent researches, that lesions of the macular region only affect the pupillary reaction. Thus, also it has been found that primary optic atrophy does not affect the reactivity until vision is diminished to 3-10 and that from this point on the two proceed pari passu.

The patient's subjective sensibility to difference of light can also be measured, and it has been found that so long as the light differences are sufficient to cause the pupil to react, the individual can also discriminate between them subjectively and vice versa. Lack of harmony between the two is found only in ocular hysteria, simulation and cortical amblyopia. Each of these again can be differentiated. Because of the above diagnostic possibilities and the fact that, since we can numerically measure, not only the direct, but also the consensual reaction, we are in a position in many

* Read before the Section on Eye, Ear, Nose and Throat of the Medical Society of California at Yosemite National Park, May 16, 1922.

cases to localize obstructions or lesions in the different parts of the reflex arc. It is for this reason that the instrument is called the "Differential Pupilloscope." In addition it enables us to positively diagnose a "sluggish reaction" before this becomes apparent by our best clinical methods. On the other hand, in a series of 108 neurological cases, which are reported elsewhere by Dr. Mehrtens and the author, twelve cases which had clinically been diagnosed as Argyll-Robertson pupils, because of their sluggish reactions, were proved by the pupilloscope to be normal. This discrepancy between our clinical and pupilloscopic examinations is accounted for by the fact that the former are based on the arc, the amplitude, speed, etc., of the reaction. These factors obviously vary, not only according to the judgment of the individual observer, but also in themselves inasmuch as they are influenced by the structure of the iris. Thus the senile iris and sphincter are stiffer than a young one; a brown iris stiffer than a blue one. These factors do not, however, affect the reactivity as tested by our method. It is true, on the other hand, that the results obtained with the instrument require an exact ocular examination and considerable personal experience on the part of the observer.

In practice I have found the method of particular value in the following:

1. Deformed pupils, if pathological, show diminution of reactivity of part or of the whole sphincter.
2. Anisokoria. If due to pathological lesion, the reactivity is affected. In congenital cases it is normal.
3. Early diagnosis of Argyll-Robertson as well as other pupillary lesions such as iridoplegia and ophthalmoplegia interna.
4. Definite diagnosis of Argyll-Robertson pupil in presence of optic atrophy, opacities of the media, or even of synechae, so long as in the latter case a portion of the pupil is not mechanically impeded in its freedom of movement.

The value of the above is evident to any one familiar with the significance of pupillary lesions. It is a matter of general knowledge that the true Argyll-Robertson pupil (reflex iridoplegia) occurs only in neuro-syphilis. It is often isolated and may precede by many years all other signs of the disease. At the present time it is of interest to note that in encephalitis lethargica the Argyll-Robertson pupil does not occur, whereas ophthalmoplegia interna is frequent.

Lay Control of Medicine—Lay control and dictation of the management of the institutions in which medical men are interested directly or indirectly is bound to come unless something is done to prevent it. Not alone this, but lay control of everything pertaining to the practice of medicine eventually will come unless the spineless doctors who fail to see the growing tendency of the times awaken to the danger and put on their fighting clothes in an attempt to save a reasonable amount of independence for themselves. This is no idle dream, and those who think differently will have occasion to learn the truth perhaps when it is too late.—Indiana Medical Journal, September 15, 1922.

INTRA VITAM BONE MARROW PUNCTURE IN PERNICIOUS ANEMIA*

By ERNEST H. FALCONER, M. D., San Francisco and LAIRD M. MORRIS, M. D., San Francisco

Laird M. Morris has devised a small drill, carrying an outer casing and driven by a dental engine, the drill being attached to the dental engine in the same manner as an ordinary dental drill. This drill will readily penetrate the cortex of the long bones. When this is accomplished the drill proper, marked in the illustration (B) is withdrawn from the puncture wound, leaving the casing (C) in situ. Through this casing a sample of the marrow is reamed out with the screw-like instrument marked (A).

TECHNIQUE OF OPERATION

In our experiments we have always selected the tibia for the purpose of puncture on account of its accessibility. The site usually chosen is about the juncture of the middle and upper third. The skin over this area is carefully sterilized with tincture of iodine and alcohol, and 2 per cent novocain used to accomplish local anaesthesia both of skin and underlying periosteum. The skin incision need not be over 1 cm. in length, being careful to divide the periosteum underneath. Only moderate pressure is used to force the drill down as it is penetrating the cortex of the bone. As it works its way down through the bone the drill usually becomes heated and cauterizes the puncture. The technique concerning a sterile field and asepsis should be impeccable. As soon as the cortex is pierced and the drill removed with the casing in situ, the small screw-like instrument is carefully passed down the casing to the marrow. After several turns it is lifted out and the marrow smeared on sterile cover slips attempting to secure a thin, uniform distribution on the cover slip. These smears are dropped into absolute methyl alcohol for fixation and are stained with the May-Grünwald stain, counterstained with Giesma's stain for good cell differentiation. Wright's stain may be used, but does not seem to be quite as satisfactory as the above method.

INTREPRETATION OF BONE MARROW SMEARS

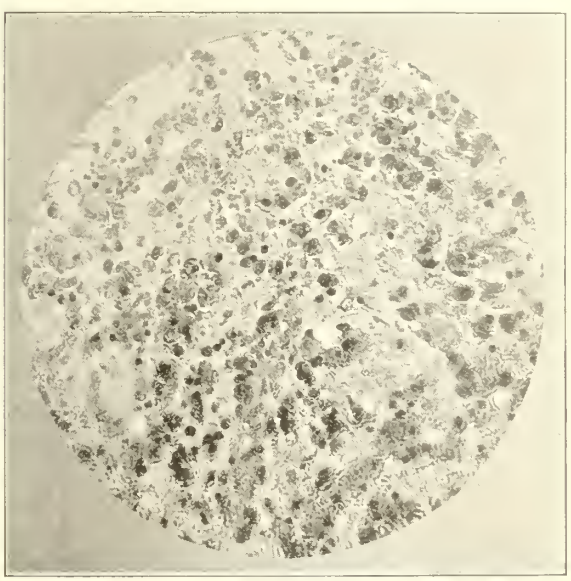
After one has secured a bone marrow smear and prepared it the interpretation of the specimen is fraught with considerable difficulty. It will be evident to any one familiar with blood work that several smears must be studied. In the leukemias the marrow smears are not so difficult to interpret as the marrow is very cellular and the type of cell is suggestive of the condition. In pernicious anemia the interpretation is far more difficult and a discussion of this problem involves a consideration of the accepted ideas of bone marrow pathology in this disease. The viewpoint put forward by Ehrlich in 1898 that pernicious anemia is a primary disease of the bone marrow, a "megaloblastic degeneration," i. e., a degenerative change in which the marrow reverts to its embryonic type of red cell production, has not been fully supported by clinical observation and experimental evidence.

---

* Read before the Section on General Medicine of the Medical Society of California at Yosemite National Park, May 16, 1922.

Megaloblasts and macrocytes have been found in the blood and in the marrow in other conditions, i. e., other types of anemia and the condition has been reproduced experimentally in animals by Bunting, with hemolytic toxins; for example, ricin. It would appear, therefore, that the changes in the marrow in pernicious anemia are secondary and represent an effort to compensate blood destruction rather than the marrow being the primary site of a disease which is characterized by faulty blood regeneration. If marrow changes are secondary and represent "broken compensation" from overwork how will the marrow in progressive pernicious anemia differ from that of other severe anemias. As a matter of fact the widely prevalent idea that the marrow in this disease is always a red marrow is very probably incorrect. Also there are undoubtedly severe chronic anemias where the marrow, at first very active, later becomes exhausted, and is indistinguishable from that found in pernicious anemia. The degree of hemolysis

Cut 1
This marrow smear is diluted with normal Saline solution and cells are sparsely distributed



Cut 2
Microtome section of marrow from patient where splenectomy was performed

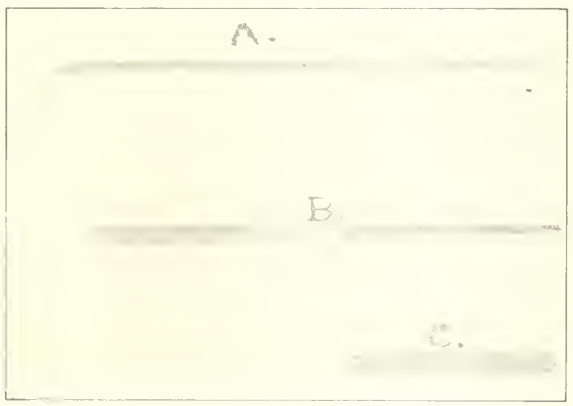
probably determines to some extent the formation of red marrow in pernicious anemia. For example, there is a type of case called attention to by Minot in Oxford Medicine where the disease comes on late in life and the toxic manifestations are chiefly apparent in the nervous system as a postero-lateral sclerosis of the spinal cord. Following is a brief synopsis of such a case. F. C., a male, entered the University of California Hospital first in 1918 aet. 59. Complaints: Weakness, numbness and tingling of hands and feet, diarrhoea, dizziness and "creepy" sensations. Examination showed: Tongue red, smooth; abdomen, slightly distended and sensitive to palpation; superficial reflexes exaggerated, especially knee jerks; gait, ataxic and spastic; Rhomberg present; Wassermann negative; spinal fluid negative. Gastric analysis showed no free HCL. Stool examination negative for parasites. Duodenal contents showed no urobilinogen; urobilin present in four dilutions, giving 800. Hbg. 45 per cent; red cells 2,100,000; white cells 7200; differential polymorphs 71; lymphocytes 24; eosinophyles 5 per cent.

Since this admission date the patient has entered the University of California Hospital four times, each time apparently in a relapse. After rest in bed in the hospital with one or two transfusions his red cells and hemoglobin rise, his symptoms improve and he leaves the hospital. On his last entry, November, 1921, marrow puncture was performed, and while his marrow was not definitely yellow, it certainly was not cellular. We have examined the marrow of three other cases almost identical in type with the above case and the marrow in each case was not cellular and did not impress us as being an active marrow. It would seem in these cases as if blood destruction is never very marked, nor on the other hand, is marrow activity, especially of the long bones, ever very marked. The toxins that cause the combined sclerosis of the cord depress the marrow activity and we get a sluggish marrow. According to Minot in Oxford Medicine, these cases die of their cord changes, rather than their anemia.

Contrast this type of case with the following case: H. B., a male aet. 46, dates his symptoms back to August, 1920, when he noted a yellowish tint to his skin. He also noted dyspnoea, palpitation weakness. During October, 1920, he became so weak that he could not walk so he entered the San Francisco Hospital. In one month he was discharged much improved and he returned to rather hard physical labor. He remained well up to April, 1921, when he again ceased work on account of weakness. On May 27, 1921, he again entered the San Francisco Hospital. At this time he complained of yellow color of skin, weakness, numbness and tingling of hands and feet, abdominal pains and distension, sore mouth and tongue. Examination showed a weak, apathetic man with lemon yellow tint to skin. Tongue smooth and red. A blowing systolic murmur over apex and base of heart; spleen and liver edge

palpable; patellars hyperactive. Urine shows urobilin present. Gastric contents show no free HCL. Stool examination negative for intestinal parasites. Wassermann negative. Blood examination: hbg. 20; red cells 864,000; white cells 2000; differential polymorphs 60; small mononuclears 25; large mononuclears 15 per cent; Smear shows macrocytes, microcytes, poikilocytes, a few normoblasts. Reticulated red cells 4 per cent. Fragility of the corpuscles .45-.38. Shortly after entering hospital a marrow puncture was performed showing a red marrow, very cellular, with evidence of activity—see cut of bone marrow smear No. 1. Many of the cells showed mitotic figures and also what we considered might be direct division by splitting up of nuclei. This patient left the hospital in July after two transfusions feeling very well. He returned to rather heavy physical labor. Shortly after leaving the hospital he was married.

We have performed marrow puncture in seven cases of pernicious anemia, where the diagnosis



Showing actual size of drill and instrument for reaming out the marrow

seemed quite certain and there were only two marrows that showed the presence of a number of cells containing mitotic figures in the nuclei. The other case is that of a young woman with marked evidence of hemolysis, but very little evidence of blood regeneration, as judged from a study of the peripheral blood. She showed on examination of the marrow a moderate number of cells scattered through the smear. We considered her marrow to be hyperplastic. About two weeks after marrow puncture she was subjected to removal of the spleen. Cut No. 2 shows a section of the marrow obtained at autopsy, as she only survived the splenectomy about three weeks. This section shows what appears to be considerable cellular activity in the marrow of the tibia following splenectomy. Two transfusions before splenectomy were apparently without avail in stimulating the marrow of the long bones.

The majority of the cases, diagnosed as pernicious anemia, and in which marrow puncture has been performed by us, have yielded a marrow showing very few signs of activity as judged by number, uniform distribution of cells and presence of diversified types of cells with amitotic and mitotic divisions of nuclea. This has been due in part at least to the fact that we have been dealing, for the most part, with cases of long duration where the marrow has been practically exhausted. It seemed best, for reasons which are obvious, to begin our work with cases of this type. The data here presented is fragmentary and can not be used for critical analysis, our purpose in this paper being to present a method which we believe can be used to advantage in the study of pernicious anemia. Our basis for such belief is that we feel, in order to give intelligent prognosis in primary anemia, it is necessary to balance the degree of blood destruction against the degree of blood regeneration, as evidenced by direct study of the marrow, rather than by study of the peripheral blood alone. The method also enables one to study the effects of agents thought to be marrow stimulants. Such studies are now under way with reference to the effects of different dosages of X-Ray on the marrow. The histological study of the marrow during different phases of the disease should yield information of definite value.

The greatest service perhaps which the method has rendered us in connection with pernicious anemia, has been to awaken an interest and desire to study the disease in its entirety and to classify doubtful cases at an earlier date than has been possible in the past.

PHYSICIANS BEGIN OFFENSIVE IN THE PROBLEM OF NARCOTIC ADDICTION

The present anti-narcotic laws are not perfect by any means, but their honest, intelligent enforcement would reduce the number of addicts very materially and simplify the whole problem very much. Physicians have allowed themselves to be placed upon the defensive in this medical and public health problem by dishonest political propaganda for a long time. At last a serious organized offensive movement has been started so that the public may be informed of what some administrative officers of our government will do with the morals, health and lives of our citizens, that they may have political control of an important part of the underworld and at the same time, in some instances at least, seeure profit to themselves.

The House of Delegates of the American Medical Association, in convention assembled, on May 23, 1922, adopted the following resolution on narcotic addiction:

"Resolved, That the House of Delegates of the American Medical Association approve House Resolution No. 258 (House of Representatives, Washington, D. C.), providing for a select committee of fifteen to inquire into the subject of narcotic conditions in the United States, the personnel of the Congressional committee to include all physicians who are now members of the House of Representatives."

House Resolution Number 258, referred to in the A. M. A. resolution, was introduced by Congressman (Doctor) Lester D. Volk. It calls for the appointment of a special committee, consisting of the fifteen physician members of Congress, to investigate the narcotic evil. This resolution, which has been endorsed by a number of National and State organizations, is a fearless exposé of some of the disgraceful methods employed in the administration of present laws, both by State and Federal

officers. The resolution in full (italics ours) is as follows:

"Whereas competent medical and administrative authorities estimate that between one million and two million persons in the United States are victims of narcotic-drug addiction, and many of these unfortunates are ex-soldiers, ex-sailors, and ex-marines, members of the American Expeditionary Forces in the late World War, and the situation arising from the existence of so large a number of narcotic-drug users has created a menace to the physical and moral welfare of the citizens of the United States; and

Whereas this condition of affairs has been complicated and aggravated by administration of existing narcotic laws in the various States and of the Harrison narcotic law by the Federal Government, and *many of the rulings of the Federal Government and the provisions of State narcotic laws and sanitary codes of municipalities of the United States, point to an organized conspiracy on the part of certain administrators and physicians to drive narcotic-drug addicts into established sanitaria purporting to treat and cure narcotic-drug addictions;* and

Whereas this conspiracy has taken the course of rulings, provisions, and regulations by the Federal Prohibition Commissioner at Washington, acting for the Internal Revenue Department of the Treasury Department in the matter of narcotic control, and by the passage of statutes by various State legislatures and the regulation of narcotic-drug distribution by various boards of health of various municipalities of the United States, which are contrary to existing medical bibliography, clinical and pathological research, and the best medical and lay experience in the handling of addict patients; and

Whereas the said medical bibliography, clinical, and pathological research, ignored in the administration of Federal, State, and municipal statutes, rules, and regulations, set forth conclusive scientific proof of the grave physical reactions in the body of an addict deprived of opium derivatives, resulting in acute discomfort, collapse and sometimes death; and pathological research shows changes in blood analyses in different stages of the withdrawal of narcotic drugs from addict patients, duplicating in every particular the phenomena evidenced in cases of acute infection and commonly recognized as disease symptoms; and medical records exist that serums extracted from the blood of animals in drug withdrawal has produced the complete symtomatology of drug withdrawal when administered to unaddicted animals of the same breed; and medical history, current and foreign, reports scores of cases of congenital addiction (that is, addiction at birth), and scores of deaths as the result of improper withdrawal of drugs; and

Whereas all of these known facts have been ignored in the administration of the Harrison narcotic law and in the administration of various State narcotic statutes and municipal sanitary codes and regulations, by the issuance of rules and regulations making it impossible for the medical profession to treat narcotic-drug addicts without fear of arrest, indictment, and conviction, or interference and persecution by the criminal authorities; and

Whereas such administration of existing narcotics, Federal, State and municipal, has resulted in an increase in smuggling, peddling, and illegal distribution of opium and its derivatives, and exaggeration of conditions in the underworld resulting from the existence of a criminal type of addicts; and such administration has resulted also in a virtual monopoly in the treatment of narcotic addict patients by privately owned and operated sanitaria promoting certain routine formulas and cures for narcotic addiction; and *it is a recognized fact among competent clinicians that the physical phenomena presented by the addict patients do not lend themselves to treatment by any specific routine treatment;* and

Whereas evasion and ignorance of these facts is rapidly increasing the criminal class of addicts, spreading addiction among the curious, encouraging smuggling, and *driving hundreds of thousands of post-operative and post-war addicts of every walk of life to doubtful cures conducted by charlatans and fakers,* and these intolerable conditions, menacing the youth of the nation and the physical and moral welfare of our citizens can be corrected only by an unbiased and fearless investigation of narcotic addiction conditions in the United States; therefore, be it

Resolved, That the Speaker appoint a select committee of fifteen, and shall include therein all members of the medical profession who are Members of the House, and that such committee be instructed to inquire into the subject of narcotic addiction in the United States, the method of handling these unfortunates, the medical addenda available regarding methods of treatment by private physicians, institutions, and sanitariums, the effectiveness of the present laws, rules, and regulations to control smuggling, trafficking and abuse of narcotic drugs, and for the purpose of drafting legislation for the control of narcotic drug addiction.

For such purposes it shall have the power to send for persons, books, and papers, administer oaths, and is authorized to sit during the session or recesses of Congress, at Washington or any other place in the United States, and shall have the right to report at any time.

The expenses of the said investigation shall be paid out of the contingent fund of the House upon vouchers approved by the chairman of the said committee and to be immediately available."

All physicians should read this resolution, as well as the discussion of the subject by Congressman Volk and others, published in the Congressional Record and elsewhere. It would be as feasible to try to clarify the waters of the Mississippi River by filtration as it would be to solve the drug addict problem by treating the addicts. In both instances purity may be obtained only by cleaning the mud out of the source.

Some administrative officers have granted permits to cultists, not educated in the actions and uses of narcotics, who claim to be opposed to the use of drugs and who are not licensed to prescribe or use narcotics by the State; they have refused publicity of the names and qualifications of some who are given permits under the Harrison law; have employed unnecessary restrictive measures to physicians and surgeons licensed by the State to prescribe narcotics; have encouraged or permitted publicity tending to criticize and embarrass educated licensed physicians, and have used this publicity as a smoke-screen to hide certain methods employed in administration of these laws.

The JOURNAL has much interesting evidence on this subject about conditions closer home. We want more. Every physician in the State is requested to continue reporting to us every instance of the dispensing or prescribing of narcotics by any person not holding a California Physician and Surgeon's license.

The drug addict problem is one of the most important medical and public health questions before the citizens of this State. Dr. Volk, after accumulating nation-wide data, says that dishonest administrative officers of the Government and a few politicians of our profession are attempting to place the blame for their misdeeds upon our profession. The physicians, hospitals, nurses and other medical agencies of California—individually and through their organizations—resent the abominable situation and may be counted upon to express this resentment effectively.

EDITORIALS

MEDICINE, MEDICAL EDUCATION AND PUBLIC HEALTH IN CALIFORNIA AFTER NOVEMBER 7, 1922

When this number of the Journal is issued, important and far-reaching proposed laws regulating medical education, public health and medical practice in this State will have been decided at the polls. No electorate has been called upon before to pass upon three more important health questions than those that will have been decided by the ballot in California on November 7. The chiropractic initiative No. 16, the osteopathic initiative No. 20, and the anti-vivisection initiative No. 28, strike at the very foundation of the health protecting and medical education standards of the State.

At this writing, two weeks before election, it is impossible, of course, to predict the outcome. Under the leadership of the League for the Conservation of Public Health, all agencies that could be interested in maintaining educational standards and public health safeguards have been kept busy informing the people in a great State-wide campaign. As individuals and as members of organizations, physicians, nurses, public health nurses, social workers, pharmacists, the presidents of our two great universities, health officers, hospitals, clinics, civic organizations, insurance companies and many other persons and groups, have cooperated. It has been very difficult to arouse and sustain the interest of some who by education and training might have been expected to take an active part in a movement of this kind. The opposition were well organized and well financed. It is believed that the seriousness of the situation and the probable consequences have been outlined clearly. There are so many measures on the ballot that the apathy of some to whom the people had a right to look for guidance on these three anti-health measures may permit passage of one or more of them. If such an unfortunate result occurs, it may prove to be the stimulus necessary to awaken educated public sentiment to its responsibility at the polls.

LIFE TABLES

If we were to believe the various propaganda life statistics that are published in endless variety from various sources, and believe them as to the thousands of lives that are claimed to have been saved by this or that effort, we could easily delude ourselves into believing that the span of life was lengthening so rapidly that we could see it grow.

Cold, reliable figures, compiled by adding machines from the census of 1920, are beginning to be issued and they are disillusioning. Tables covering 74 per cent of the total population of the nation show the expectation of life at birth is 55.23 for white males and 57.41 for white females.

PHYSICIANS' OFFICES AS "HEALTH CENTERS"

One of the important resolutions passed unanimously by the House of Delegates at the last annual meeting of the State Society is printed on the front cover of this number of the JOURNAL. Contained in the minutes of the House of Delegates, as part of that resolution, is the following note:

> The State Society will supply each of its members with appropriate blank forms for this purpose, and will furnish one to any citizen who desires to use it. One of these forms presented to any member of the State Society in any part of the State will insure the courtesies and special consideration that his condition warrants and, in addition, he will receive the same sympathetic, confidential, constructive help that is given to the person who is able to pay fully for all that he requires. In carrying out this program, physicians reserve the right, when they think wise, to check up on the accuracy of the applicant's statements in an unobtrusive and sympathetic manner, in exactly the same way as those reports are now being checked up by clinics and other welfare organizations. Members also reserve the right to refer applicants for special consideration to other physicians under the same conditions and for the same reasons that they would refer patients paying regular fees. Any sick person in any part of the State of California who fails, for any reason, to secure adequate medical attention is requested to communicate with the secretary of the State Medical Society, 1016 Balboa Building, San Francisco.

It is the general impression among physicians, and the resolution itself so states, that it is a re-emphasis of the practices and policies of physicians everywhere at all times.

The blank form referred to in this resolution has been prepared and is now being considered by the Council for publication. It will be ready to distribute to members who desire to use it very shortly. Many already have requested this form and further information as to how they may make their activities conform with the spirit of the resolution.

There are two outstanding features of this resolution, the most important being that physicians are ready to render service to any person requiring professional care; that those who are able to pay the physicians' regular fees for this service should do so, those who are able to pay part should do so, and those who are unable to pay any of the fee should have the service just the same; all services, regardless of the status of the patient, to be rendered in the same high grade, confidential, sympathetic manner. The other important feature in the resolution is that it never has been, and is not now, necessary to interpose any agency not under the direct supervision and control of competent members of the medical profession between the physician and his patients.

It has been said by some that, if the spirit of this resolution were applied, physicians would not be able to give adequate care to all of the ambulatory sick in this State, particularly in certain congested centers. The facts are, that members of the medical profession *now* take care of all of the ambulatory sick, as well as those who are bedridden and require more time, and furthermore the

problem in the aggregate is not as large as some people seem to think. If all the sick people in the State of California, of whatever class, kind and condition, were divided up equally among the seven thousand educated physicians practicing in this State, they would have less than twenty sick people each to look after. If the ambulatory patients were so divided, the doctors' offices of this State would average less than ten visits per office per day.

The primary consideration in the carrying out of this or any other resolution or policy of the medical profession is, that the sick people, regardless of class of sickness, their place of residence or any other consideration, should have adequate medical care. This medical care should be available to all ambulatory patients in physicians' offices and to all others in their homes, hospitals or wherever else they may be. The resolution of the State Society is an effort to make these facilities available in a practical manner.

THE "TRAINED ATTENDANT"

The problem of the "trained attendant," the "sub-nurse," the "apprentice nurse," the "nursing aid," the "practical nurse," or members of that group of persons attending the sick who have less education than the nurse, is near the surface in the minds of all people interested in the care of the sick. These "chiropractors of the nursing profession," as one nurse recently designated them, are or are not necessary. Their future development will depend upon just one thing, and that is the solution of the problem of nursing education. If nurses or their supporters are required to invest so much time and money in education that their "investment" makes a balanced compensation more than people can pay, and if, also, the knowledge obtained makes the nurse more nearly approach the physician in her function and, consequently, less likely to perform what is usually designated upper-class maids' work, then the "trained attendant" (by some name) surely will become an important factor in the agencies of medicine. Theoretically two classes of technical service rendered by the thoroughly educated nurse and the semi-educated helper look attractive, but the actual practical working out of the theory is contrary to human nature and to past experience. Leaders of the nursing phofession have a serious responsibility in determining the future of their profession. If the League of Nursing Education could see a clear solution of their problem and act NOW they could control the situation, but prolonged discussion and reports of special committees are not getting them ahead very fast. In the meantime the world is moving and there is real danger that public opinion and practice may have determined the final result before experts get ready to act. We believe that the medical profession is ready and willing to help the nurses with their program, but they cannot help very much until the nurses agree upon a program. It would seem that leaders in nursing education might learn a lesson as to the dangers of unwise educational policies from the history of medical education. It remains to be seen whether the nurses will profit from the mistakes of the medical profession or whether they also must provide for cults in their own profession before they wake up. Whatever the end result, any worthwhile information on the subject is interesting, and for that reason the following is abstracted from an address by A. K. Haywood, M. D., to the graduates of the second class of "attendants" in Montreal:

"The trained attendant first made her appearance in Boston in 1912 through the Household Nursing Association, but it was not until 1918 that a definite course of training was established, and since that time several schools for trained attendants have been founded in Canada and the United States.

"You are no doubt aware that the course which you have just completed is open to criticism, but it is mainly the criticism that one finds directed against any new project or innovation that tends to deviate from tradition or long established custom.

"It is quite unlikely that these schools for attendants would have been established had there not been a demand for the class of service that you have been trained to render. This demand is urgent at the present time, and I have no doubt that you will find plenty of opportunities to practice your calling in this city, and it is in view of this probability that I would sound a note of warning.

"A knowledge of the needs of this community convinces one that there are scores of families who, when illness overtakes them, will find in your services a blessing. I do not wish to intimate that you will be sufficiently versed in the art of nursing to take the place of the graduate nurse. Her position and knowledge are only made possible after three years of the hardest kind of work, study and sacrifice, and it is only natural that she will view graduation exercises as you have them this evening with apprehension; but I feel sure that the graduate nurse will realize in time that it is possible for her work to be supplemented by a body of women such as you represent. One cannot help but feel that in many cases of chronic illness, in convalescence, and in caring for children, the employment of a graduate nurse would tend to produce such financial embarrassment in that family that would make her employment impossible, nor is it right that on this account some form of service should not be available for this class of patient. . .

"Your course is still in its infancy. I understand that you are the second class to graduate, and to you is entrusted a great deal of the future success of this venture. You can rest assured that you will be watched with a great deal of interest, and there is no doubt that your mistakes and shortcomings will be made capital of to the detriment of this cause.

"This course which you have just taken will undergo many changes. I hope I will not be misjudged if I venture a few suggestions as to those changes that at the present time might be profitably adopted. I cannot help but feel that your usefulness would be materially increased had it been possible for you to have supplemented your theoretical

work with practical work in institutions that lend themselves to your particular class of work. By that I mean institutions for incurables, convalescents, certain classes of children's hospitals, or even small general hospitals without training schools in which there is difficulty in securing probationers. The question is bound to be asked why not general hospitals with training schools? The answer is that experience has proved in those hospitals that have combined the attendants' course with the nurses' course that it has not been successful. The attendant has had relegated to her the most menial duties of the wards without the interesting nursing care to make this drudgery bearable. There is inevitable jealousy and friction between the two classes of pupils."

DANGERS TO PHYSICIANS IN NARCOTIC SITUATION

Occasionally physicians, through misconception of law, make serious mistakes in their observation of the Harrison Narcotic Act of the State Pharmacy Act. It appears certain enforcement agents of either the National or State Government find pleasure in taking advantage of even the smallest technicality in accusing a physician of violation of the narcotic law.

Several physicians guilty of only technical violation have been arrested. Frequently the charge is prescribing a narcotic not in good faith. To such a charge a physician makes himself liable should an individual come to his office pleading sudden illness and asking for a narcotic. It occasionally happens that an individual will come to the physician's office stating that he is an habitual user, requesting a tablet or two or more to tide him over until he can reach some alleged destination. Valuable information on this subject may be found on pages 17, 18 and 19 of the directory published by the Board of Medical Examiners and distributed to every individual licensed to practice in this State.

Every physician should familiarize himself with Section 8 of the Pharmacy Act, which requires that a report by registered mail, addressed to the office of the State Board of Pharmacy, must be made by a physician undertaking the cure of an addict "within 24 hours after the first treatment."

When a physician has been arrested on technical violation of any of the above, it has been reported that he is advised to plead guilty, pay a nominal fine, usually $100, and thus escape unpleasant publicity or notoriety. Such advice should be refused because admission of guilt forms a part of the court records, puts a stigma upon the physician, and makes it incumbent upon the Board of Medical Examiners to review the case, with the possibility of revocation of license as provided under Section 14 of the Medical Practice Act. They are also easy to punish because they have both reputation and social standing to consider.

We cannot be overzealous in advising physicians not to plead guilty of infraction of the law, unless they are actually guilty, without first consulting our office. Physicians are quick to relieve distress, thus making them easy prey.

OF SUCH ARE STATISTICS MADE!

According to the Sacramento "Union" a large program of medical examination and welfare work is being carried on for the children of Sacramento County under the jurisdiction of the local chapter of the Red Cross and Mr. Hughes, city superintendent of schools, and aided by nurses.

"Three hundred and eighty-seven youngsters were weighed and measured, and 183 were given a physical examination by the nurse." It is further stated that the welfare work in the city of Sacramento has become active with the opening of the fall term of the schools. This work "will be handled directly by a staff of three, consisting of one director and two nurses, who will watch the health of Capital City youngsters with a professionally trained eye. Heretofore the health of the Sacramento school children has been observed by the director of physical training." When nurses make physical examinations and "watch the health of children with a professionally trained eye" under the direction of a superintendent of education or a "physical director," what may we expect next? School teachers sometimes, and school nurses more often, are heard to say that they have added the practice of medicine to their other duties. What do the physicians of Sacramento think of this procedure?

CORRESPONDENCE COURSES FOR PUBLIC HEALTH NURSES

There was a time when correspondence courses for physicians, nurses, engineers and other professions were in vogue. Then the light of publicity was turned upon these institutions and most of them disappeared. Out of the social, educational and economic chaos of the last few years the idea of correspondence courses appears to have been revived. Some of the institutions offering these courses and advertising them so extensively are of such questionable character that they do not require any special consideration. However, it is a matter of interest and concern to physicians, nurses and other legitimate health workers when the health service of a great State, supported by two well-known universities, enters this field and proposes to educate public health nurses by correspondence. In a mimeographed news sheet recently "released" this combination of organizations state that they have had 287 applications for enrollment in the first course, of which 229 have paid the matriculation fee and have been accepted.

CANCER WEEK

Cancer week for this year is November 12 to 18. The purposes of Cancer Week are now so well recognized by the medical profession that it ought to be necessary only to call attention to the dates to secure the co-operation of physicians in the efforts of the American Society for the Control of Cancer.

STATE SOCIETY

ABSTRACTS FROM THE MINUTES OF THE 134th MEETING OF THE COUNCIL OF THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA

(Held in Pasadena, Friday, September 8, 1922.)

(The complete minutes of this and all other Council meetings are on file in the office of the State Society and are open to any member of the society.)

Present: Brainerd, Edwards, Kenyon, Bine, Parkinson, DeLappe, Kiger, Hamlin, Carrington, Van Zwalenburg, Kress, Paterson, McArthur, Johnson, Musgrave, General Counsel Peart.

Absent: Pope, Ewer, McLeod and Parker.

Program for 1923 Meeting of State Medical Society—The following program for the State meeting in 1923 was presented by the Publicity Bureau to the Council. This program was endorsed by the State Program Committee and later approved by that committee:

The State Society will hold its regular annual meeting on Friday and Saturday, June 22 and 23, 1923, preceding the American Medical Association meeting Monday to Friday, June 25 to 29, 1923. The outline of the program for this meeting will be as follows:

1. Meeting of the Council—Thursday evening, June 21, at 8 o'clock.
2. General Session of the State Medical Society—Friday morning, June 22, at 10 o'clock.
3. Section Meetings, each section to meet separately—Friday afternoon, at 2:30 o'clock. Each section to hold only this one meeting. This to transact such business as is necessary and to read a full program of papers by title. One or a few papers may be presented in full at the option of the sections.
4. Meeting of the House of Delegates and meeting of the Council with officers of county societies and section officers—Friday evening, June 22, at dinner.
5. General Meeting—The League for the Conservation of Public Health—Saturday morning, June 23, at 10 o'clock.
6. Meeting of the House of Delegates—Saturday afternoon, June 23, at 2:30 o'clock.
7. Meeting of the Council—Saturday evening, June 23, at dinner.

Articles of Incorporation of Medical Society of State of California—General Counsel Peart read the present articles of incorporation and discussed the subject generally, stating that at this time it would be inexpedient to proceed with this matter to a definite conclusion and recommending that this matter be held under advisement until more definite information could be obtained. This action was approved by the Council, and a later report will be rendered by the General Counsel.

Woman's Auxiliary to State Medical Society—The constitution and by-laws of the Woman's Auxiliary to the State Medical Society of Texas, with explanatory letter of its activities, was considered. The secretary discussed the matter fully with a view of informing the Council regarding what might be expected from the formation of such an auxiliary to the California State Medical Society. Upon motion of Kress, seconded by Parkinson, it was

Resolved, That the Publicity Bureau investigate this matter and report further before taking action.

Relation of Section Officers to Central Office of State Medical Society—Upon motion duly made and carried, it was unanimously

Resolved, That the relations between officers of sections and the central office of the State Society should be more intimate in the handling of affairs which arise from time to time throughout the year; and further, that conferences and consultations between the State Society and these sections on such subjects should be encouraged; and further, that such section officers are, so far as the constitution and by-laws of the American Medical Association and the State Society permit, officers of the State Society, with duties as above outlined in addition to those of arranging and conducting the programs for the annual meetings.

California Association of Radiographers—The resolution on this subject passed by the House of Delegates was brought up for consideration, by the Publicity Bureau May 26, 1922, and the secretary was instructed to forward a copy of this resolution officially to the California Assocaition of Radiographers, with the following letter of transmittal:

"Your letter dated May 11 was duly received, but it was impossible for the Publicity Bureau to meet with you prior to the annual meeting of the State Medical Society, which convened at Yosemite May 15.

"Your letter was duly placed before the Council of the State Society. Following the introduction of a resolution upon this subject in the House of Delegates, the entire matter came before the Council for its recommendation and the enclosed resolution was unanimously recommended for passage to the House of Delegates, and thereafter unanimously adopted by the House of Delegates at its meeting held May 17, 1922.

"I am instructed by the Publicity Bureau at today's meeting to forward the enclosed copy of the resolution to you, and to request that you give it your consideration as soon as possible and advise the Publicity Bureau of your attitude thereon."

Associate Secretary—The Publicity Bureau approved the selection of Dr. Howard H. Johnson as associate secretary, with the understanding that the matter be brought to the attention of and secure the endorsement of the Council.

Industrial Medicine—A committee on the study and consideration of the proposed special plan for Industrial Medicine Practice, consisting of Bine, Parkinson, Graves and Johnson (Graves absent) discussed the proposed plan and, upon motion duly made and carried, it was unanimously

Resolved, That a special committee consisting of James H. Parkinson, chairman, and George W. Goodale, Lester Newman and Howard H. Johnson be appointed to draw up plans for carrying out industrial medicine practice through the State Medical Society; and further, that they draw up a fee schedule; and further, that said plans and fee schedule be completed and referred to the Publicity Bureau and Committee on Industrial Accident Work for criticism or approval.

Question of Moving the Office of the State Society—The matter of moving the office of the State Society was considered by the Publicity Bureau, as removal had become necessary because of requirement that a lease be signed for a period of three years at an increased rental guaranteed by an individual doctor or group of doctors, if the offices remained in the Butler Building. It was the recommendation of the Publicity Bureau that the offices be moved to the Balboa Building and that the secretary be authorized to make the necessary arrangements, as the above requirements do not have to be met in the Balboa Building. Also there is a decreased rental with one room less than now occupied in the Butler Building. This action was approved by the Council.

Hospital Associations—Letters and literature from various "hospital associations" were presented and discussed. The secretary-editor was instructed to write a series of articles for the Better Health Service of the League for the Conservation of Public Health on "Good and Bad Hospital Associations."

Publicity Bureau Meetings—The matter of the Publicity Bureau meetings was taken up and it was voted that the Publicity Bureau meet the first and third Thursday of each month at the office of the State Society, at noon.

Harrison Narcotic Act—The secretary-editor was instructed to write an editorial for the Journal, giving the dangers to physicians in the narcotic situation. It was suggested that he include in this

article all the technical trivialities by which doctors are endangered.

Appointment of Officers for New Sections—Upon recommendation of the Publicity Bureau, the Council approved the appointment of the following officers for the new sections created at the 131st meeting of the Council:

1. Section on Physiology, Chemistry and Pharmacology, including Physiological Chemistry, Biological Chemistry, Pharmacy, Chemotherapy, and similar allied sciences—Chairman, Walter C. Alvarez, San Francisco; secretary, W. D. Sansum, Santa Barbara.

2. Section on Anatomy, including Surgical Anatomy, Embryology, and similar closely allied sciences—Chairman, I. S. Ritchie, Loma Linda; secretary, C. Latimer Callander, San Francisco.

3. Section on Applied Biology, including Parasitology, Serology, Immunology, and similar closely allied subjects—Chairman, Alfred C. Reed, San Francisco; secretary, John V. Barrow, Los Angeles.

4. Section on Dermatology and Syphiology—Chairman, Howard Morrow, San Francisco; secretary, Moses Scholtz, Los Angeles.

Incorporation of Indemnity Defense Fund—The general counsel reported the result of his investigation of the proposed establishment of the Indemnity Defense Fund as an independent corporation in conformity with a resolution passed by the Council at its 133rd meeting in Yosemite, May 18, 1922. After an extensive investigation of this subject he expressed the opinion that the most feasible method of procedure would be to incorporate the Indemnity Defense Fund with capital of at least $100,000 in excess of all liabilities. The general counsel discussed the record of other companies from reports on file, which seemed to show that the formation of such a company, with the advantages available in the present Indemnity Defense Fund in its relation to physicians of the State of California, would be advisable and advantageous.

Upon motion of Parkinson, seconded by Paterson, it was

Resolved, That the present committee continue its efforts to obtain the required subscriptions of capital stock by canvass of the members of the Society and proceed to draft necessary papers, and that a further progress report be made to the council at a special meeting, if necessary.

Medical Service for Disabled Veterans of the World War—The secretary submitted the offer of medical and hospital service to disabled veterans of the World War, made by the Medical Society of the State of California in conjunction with the same offer by the Hospital Section of the League for the Conservation of Public Health. Upon motion of Parkinson, seconded by McArthur, it was

Resolved, That the council officially endorse the action of the secretary in offering the services of the medical profession of the State of California to the Disabled Veterans of the World War.

Resolution from the Section on Anesthesiology—The secretary presented the following resolutions from the Section on Anesthesiology, which they requested be brought to the attention of the Council of the State Society:

"Resolved, That the Section on Anesthesiology of the California State Medical Society hereby expresses its appreciation of the House of Delegates and Council for its creation and hopes through its activities in the future to extend the advancement of the specialty in every possible way.

"Whereas, the protection and safety of human life is a paramount issue in the practice of medicine, therefore, be it

"Resolved, that the Section on Anesthesiology endorses the action of the Section on Radiology in eliminating the technician from this vital phase of medical practice, and further, be it

"Resolved, that the Section on Anesthesiology approves and urges the continued activity of the California State Medical Society in eliminating the lay technician from the practice of anesthesia."

Action by the Council: Upon motion of Parkinson, seconded by Hamlin, it was

Resolved, That this resolution be accepted and placed on file.

Gorgas Memorial—The secretary presented the matter of the Gorgas Memorial data, which was fully discussed. Upon motion of Parkinson, seconded by Kress, it was

Resolved, That the council request the president of the State Medical Society, in accordance with the request of the American Medical Association, to appoint a Statewide committee for the purpose of securing funds for the Gorgas Memorial.

Industrial Medicine—(Note—George W. Goodale, Lester Newman and Gayle G. Moseley were called in to discuss this question and Dr. Goodale's "Plan of Operation.") Goodale presented his revised "Plan of Operation," together with proposed "Special Fee Schedule," and the whole matter was fully discussed.

Action by the Council: Upon motion of Parkinson, seconded by Bine, it was

Resolved, That the whole matter be referred to the Committee on Industrial Accident Work for conferences with Goodale and any persons who may be considered interested in the matter, and that the committee report back to the council when ready to submit a digest of the matter; and further, that the secretary be instructed to call a special meeting of the council to hear this report.

Sins and Sorrows of the Colon—A. F. Hurst, discussing this subject in the British Medical Journal of June 17, says: "The sins of the colon are its diseases. But I sometimes wonder whether it is not more sinned against than sinning, for whether with attacks from above with purges, attacks from below with douches, and frontal attacks by the surgeon, the sorrows are numerous and real.

"If the fortunes made from purgative pills had been devoted to hospitals which treat the victims of their abuse, the financial problem of the voluntary hospitals would have been solved. About ten million pounds were expended in 1921 on patent medicines, the majority of which contained purgatives.

"On several occasions, when I have been asked to decide whether the operation of colectomy, which had been recommended for 'intestinal stasis,' should be performed, I have found that all the symptoms disappeared on giving up purgatives and adopting some rational treatment. It is said that the description Gulliver gave the Houyhuhnms of the habits of his fellow-countrymen is as true today as it was in 1727: 'They take in at the orifice above a medicine, equally annoying and disgusting to the bowels, which relaxing the belly drives down all before it; and this they call a purge.'

"Pliny tells how Egyptians learnt to wash out their bowels from observing the habits of the ibis: 'He washes the inside of his body by introducing water with his beak into the channel, by which our health demands that the residue of our food should leave.' It is cruel to deprive the ibis of his claim to this epoch-making discovery, but the truth must be told: the ibis does not give himself a douche, but after washing his beak in water he oils it in his preen gland, which is situated near the anus, in preparation for preening his feathers.

"In the seventeenth century the enema reached the height of its popularity. It is recorded that Louis XIV received several thousand intestinal douches in the course of his life, and that the pious Duchess of Alva treated her sorely ill son with enemas of an emulsion of religious relics. Unhappily, they failed to save him.

"The last twenty years have seen a remarkable revival in the popularity of the intestinal douche, a popularity which has led at times to its indiscriminate use for conditions in which it was not suitable. It is a valuable remedy, but its precise indications require to be defined."

COUNTY NEWS

ALAMEDA COUNTY

Alameda County Medical Association (reported by C. L. McVay, M. D., secretary-treasurer)—At the October meeting Herbert Samuels and Mr. Gould, executive secretary of the proposed International Public Health and Safety Exposition, addressed the meeting on the plans contemplated by the Executive Committee of the Exposition. These plans were more fully commented on by Alvin Powell.

The evening program consisted of a paper read by A. H. Rowe, "Diagnosis and Treatment of Thyroid Disease as Controlled by the Metabolic Rate." (1) Comments on technique and interpretation of the metabolic rate. (2) Pathology of thyroid. (3) Clinical use of rate determination in adenoma, hypertoxic goitre and hypothyroidism.

The paper was illustrated by lantern slides and discussed by Moffett and W. H. Strietmann.

George Rothganger read a paper on "Paralytic Pes Cavus." (1) Mechanism of the development of paralytic talipes in general. (2) The special factors in pes cavus. (3) Methods of treatment. (4) The extension of operative measures to other allied deformities. M. L. Emerson led the discussion on these papers.

In November the Fresno County Society will present a program before the Merritt Hospital staff council. This program reciprocates one which was given before the Fresno County Society on April 17, 1922, by the Merritt Hospital staff.

BUTTE COUNTY

Hospitals, Clinics and Laboratories (reported by Dr. J. O. Chiapella, secretary Butte County Medical Society)—

Enloe Hospital, Chico, 35 beds; Dr. Enloe, executive.

Oroville Hospital, Oroville, 35 beds; Miss Agnes Curran, executive.

Butte County Infirmary at Thermoletis, 100 beds; J. F. McDonald, executive.

Sisters' Hospital at Chico, 20 beds.

Eye, Ear, Nose and Throat Hospital at Chico, 3 beds; (emergency only) Dr. J. O. Chiapella.

Chico Health Center Clinic, Miss L. Wade, district nurse; President Dr. J. O. Chiapella, executive.

X-Ray Laboratory at Enloe Hospital, Dr. W. B. Johnston, Dr. R. E. Poole, Dr. D. H. Moulton, Dr. P. L. Hamilton.

FRESNO COUNTY

Fresno County Medical Society (reported by Thomas F. Madden, secretary)—The October meeting of the Fresno County Medical Society was held at the residence of the president, G. W. Walker, on the evening of October 3, 1922. Those present were: Aller, Anderson, Barrett, Bell, Brown, Broemser, Collins, Couey, Cross, Craycroft, Ellsworth, Goldberg, Hayden, Jamgotchian, Konigmacher, Kjaerbye, Madden, Manson, Mitchell, Miller, Montgomery, Morgan, Milholland, McPheeters, Pettis, Pomeroy, Sciaroni, Sheldon, Thompson, Tillman, Tobin, Tupper, Wahrhaftig, J. R. Walker, G. W. Walker, Weddle, Wiese, Willson, Vanderburgh, Dearborn, Quimby, Scarbora, with S. H. Hurwitz and A. S. Kilgore of San Francisco as guests and speakers.

S. H. Hurwitz gave an interesting talk on "The Newer Aspects in the Treatment of Asthma." The speaker outlined the recent work being done in the diagnosis and treatment of asthma, reminding us that much of the best work is done in the United States. Discussion by Pettis, Barrett, Tillman and Walker. A. S. Kilgore outlined the work to be undertaken during "Cancer Week," which is the week following election in November. Guy Manson is in charge of this work in Fresno County.

Fresno County Hospital—The regular monthly meeting of the staff of the Fresno County Hospital was held at the hospital on the evening of October 10, 1922. P. S. Barrett of the department of pediatrics presented a case of neuro-syphilis in a child and discussed the subject at some length. Discussion by Bell, Konigmacher, Tupper and Vanderburgh.

LASSEN-PLUMAS COUNTIES

Lassen-Plumas Counties Medical Society (reported by G. S. Martin, secretary)—The Lassen-Plumas Counties Medical Society met October 7 at the Riverside Hospital, Susanville, as guests of the hospital. The meeting was for the purpose of reorganization and electing officers, and was very successful. Several of the visiting doctors had to travel quite a long distance, and are to be highly commended for their interest in society work. Officers were elected as follows: R. W. T. Garner, Susanville, president; B. J. Laswell, Quincy, vice-president; G. S. Martin, Susanville, secretary-treasurer; C. L. Smith, Greenville, W. W. Peterson, Quincy, H. A. Collings, Johnsville, board of censors. S. M. Sproat, Portola, delegate to next State meeting with Dr. Peterson as alternate. The next meeting will be held at the same place the afternoon of the first Saturday in November, and a scientific program is being arranged. This will be the last meeting of the year, as the heavy snow will soon have the roads blocked.

LOS ANGELES COUNTY

Methodist Hospital, Los Angeles, accredited by the American Medical Association—Upon recommendation of the California committee, the Council on Medical Education and Hospitals of the A. M. A. has placed the Methodist Hospital of Los Angeles upon the accredited list in the following letter to Mr. L. G. Reynolds, superintendent of the hospital:

"The council has been pleased to receive the information furnished by you, together with that supplied by Dr. Musgrave, accompanied with his hearty recommendation of your hospital, and we are pleased to say that the council has placed the Methodist Hospital of Southern California upon the list of hospitals approved for giving the fifth year in medicine.

"We want this letter to be taken as an expression of our sincere appreciation for the good work you are doing, and our wishes that your success and progress may be continued.

"A notice of this recognition will be published in an early issue of the Journal of the American Medical Association, also in the American Medical Directory, now being revised, as well as in a separate pamphlet for mailing to medical colleges and prospective interns."

Seaside Hospital, Long Beach, accredited by the American Medical Association—Upon the recommendation of the California committee, the Council on Medical Education and Hospitals of the A. M. A. has placed the Seaside Hospital of Long Beach upon the accredited list in the following letter to Miss Alice G. Henninger, superintendent of the hospital:

"The data supplied by you directly, and also through Dr. Musgrave, and his very good recommendation of your hospital have been considered, and it is a pleasure to say that the council is placing your hospital on the list of hospitals approved for the training of interns or giving the fifth year in medicine.

"Please accept this letter as assurance of our sincere interests in the further development and progress of the Seaside Hospital.

"Notice of this recognition will be published in an early issue of the Journal, also in the American Medical Directory and ina separate pamphlet for mailing to medical colleges and prospective interns."

St. Vincent's Hospital of Los Angeles, accredited by the American Medical Association—Upon the recommendation of the California committee of the Council on Medical Education and Hospitals of the A. M. A., St. Vincent's Hospital of Los Angeles has been placed upon the accredited list in the following letter to the Sister Superior of that institution:

"We are pleased to notify you that the Council on Medical Education and Hospitals of the American Medical Association has placed the St. Vincent's Hospital upon the list of hospitals approved for giving the fifth year in medicine.

"Along with this recognition we want you to be assured of our continued interests and our sincere hope that the progress which has marked your pathway in the past, may characterize your entire future career. To this end our council will go the limit in giving any possible assistance. We know that Dr. Musgrave and his committee, representing our council, will enjoy your co-operation and the pleasure of working in your behalf."

MARIN COUNTY

Marin County Medical Society (reported by C. A. De Lancey, secretary)—Marin County Medical Society held its monthly meeting on the last Thursday of September at the offices of F. W. Jones in San Rafael. Dr. Lester Newman was the speaker for the evening. His subject was the Workman's Compensation Law of California in connection with the medical service, and the control of the Industrial Accident Commission. The following is a résumé:

It is to be understood that a patient who is a beneficiary under the Workmen's Compensation Act is primarily in the service of the insurance carrier, and not the surgeon. The legal responsibility is that of the insurance carrier. There is a triple relation between the employer, injured man, and the physician. The latter is, perhaps, the greatest factor therein; hence, he should give careful medical service, and forward careful records with promptness.

These reports are not merely red tape, but represent absolute necessity in the adjustment of cases. Payment of compensation is the prime purpose of this law; hence, delay by the physician hinders fulfillment of the law. Physicians should not withhold reports awaiting solicitation; voluntary contribution of data is essential to efficient industrial medical service.

The rendering of reports should not be assumed as a burden by the surgeon; they are nothing more than a duplication of the data which should be kept in any office where the surgeon attempts the practice of medicine. Accurate diagnosis, prognosis and treatment is absolutely essential. Necessary services only should be charged for. The surgeon is morally responsible for allied medical costs. Patients should be treated to a closure, and any lack of co-operation of the patients should be referred to the carrier. The history of the case is necessary to determine its compensability, and incidentally this is a burden, part of which the surgeon must bear. The carrier should not be censored unjustly for non-payment of bills. All patients are to be considered a private responsibility until the burden of such responsibility is shifted legally elsewhere.

Ross Sanitarium has added a unit of cottages for chest conditions. They are located high in the hills, where they are afforded much sun and fresh air and where they are spared any of the occasional fogs of that valley.

MERCED COUNTY

Merced County Medical Society (reported by Brett Davis, secretary)—The October meeting of the society was held on the 5th in the City Hall at Merced. A considerable number of the members of the society were present, and J. H. Woolsey and Burt Stevens of San Francisco were visitors.

Dr. Woolsey read a paper on "Cancer of the Lower Bowel," illustrated by lantern slides. The paper was discussed by all the physicians present.

Stevens discussed the three Anti-Health initiatives on the ballot, and invited the co-operation of members in the work of the League for the Conservation of Public Health.

Mr. Ira Hoover, architect, submitted final plans for the Mercy Hospital, which were considered and approved at a special meeting on October 7.

ORANGE COUNTY

Santa Ana Valley Hospital—Encouraging reports are received from Santa Ana to the effect that definite progress is being made in the amalgamation of the Santa Ana Valley Hospital Association and the Santa Ana Community Hospital Association under the name of the former. It is reported that preliminary agreements have been reached, and the outlook for a fine hospital for Santa Ana is very bright.

PLACER COUNTY

Placer County Medical Society (reported by Robert A. Peers, secretary)—The Placer County Medical Society met in the Masonic Temple, Auburn, Calif., October 7, 1922, being called to order by the president, Charles J. Durand. The following members were present: Charles J. Durand, Colfax; F. L. Horne, Auburn; H. M. Kanner, Colfax; G. H. Fay, Auburn; H. N. Miner, Blue Canyon; W. L. Whittington, Weimar; F. E. McCullough, Lincoln; R. J. Nicholls, Auburn; R. T. Rooney, Auburn; E. E. Ostrum, Loomis; J. A. Russell, Auburn; J. G. Mackay, Auburn; W. P. Sawyer, Nevada City; R. A. Peers, Colfax. Visitors: F. F. Gundrum, Sacramento; C. E. Lewis, Auburn.

The following physicians reported unusual cases seen in their practice since the last meeting: Miner, Nicholls, Lewis, Ostrum, Sawyer and Peers.

F. F. Gundrum of Sacramento gave an address on "The Diagnosis of Acute Conditions Presenting Bulbar Symptoms," which was discussed by the following members: Mackay, Sawyer, Miner, Kanner, Horne, McCullough and Gundrum.

W. P. Sawyer of Nevada City made a report on the three amendments in which physicians are particularly interested and which will appear on the ballot November 7. It was agreed by all present that they should endeavor in every way to place the issues on these three measures squarely before their patients and the general public before election.

RIVERSIDE COUNTY

Riverside County Medical Society (reported by Thomas A. Card, secretary)—The October meeting of the Society was held on the 9th of the month with 30 members, 10 visitors present, and 14 members absent. John C. King was transferred from active membership to honorary membership. Harold E. Morrison was transferred to Los Angeles County Medical Society, Iner-Sheld

Ritchie was transferred to San Bernardino County Medical Society, and J. W. Camp was transferred to Orange County Medical Society. Riverside Community Hospital project is going forward rapidly. Plans for a one-story 100-bed hospital have been drawn and accepted. Funds are being collected and it is hoped to start construction by January, 1923. Plans for the establishment of a full time city and county health department are under way.

An unusual case of uro-genital infection was reported by James Steinberg of Los Angeles and discussed by H. R. Martin of Riverside. Medical economics with special reference to plans for effective work, was discussed by W. T. McArthur of Los Angeles and C. Van Zwalenburg of Riverside. A buffet luncheon was served at the close of the program with Drs. Adams, Atkinson, Atwood, Bacr, Baird and Bramkamp as hosts. Mr. L. B. Saunders, director of the Riverside Community Hospital, presented the following message to the members:

"Superficially one hospital day is like another; from the smell of ether to the cry of the newborn babe; but teasing problems of hospital administration are ever present. The future Riverside Community Hospital is conceived in a spirit of service for the protection and promotion of health, possessing every known resource for the attainment of these aims. It will be a house of healing—non-sectarian—for the poor and the well-to-do alike, seeking to render a perfect service to its patients. We shall strive to become a model household where health and happiness prevail. The people of our county should be thoroughly posted as to the necessities and advantages of a modern community hospital. In such spirit we call to the doctors of the County Medical Society and ask their hearty co-operation."

SACRAMENTO COUNTY

Sacramento Society for Medical Improvement (reported by G. J. Hall, secretary)—The September meeting was held at Sacramento Hotel on the 19th of the month. President Dillon and twenty-six other members and one visitor were present. Gundrum reported a case apparently gonococcic infection that also had heart disease and nasal diphtheria. Antitoxin was administered, and a week later improvement was marked. The cardiac symptoms and findings indicated that the important infection was diphtheria. O'Brien reported an unusual case of spider bite. Beattie reported a case of tuberculous peritonitis in child four months of age. Free vomiting for several days. Temperature 100.5 per rectum. Abdomen distended. No stool; food all vomited. Controlled by serial feeding. Had been fed breast and milk from cow not tuberculin-tested and not pasteurized. Leucocyte count 13,000, 60 per cent polys. Negative Von Pirquet test. Decided to operate, thinking it an ileus. Peritoneum studded with tubercles. Post-mortem showed bovine tuberculosis. A. K. Dunlap presented the subject of "Recurrence of Symptoms Following Operation on Biliary Tract." Statistics on recurrence or secondary operations from 10 to 15 per cent of all cases. Diet during post-operative stage most important portion of paper presented. Series of forty-two cases presented, which developed symptoms after operation. Weight of opinion is toward removal of bladder. Gall-bladder was drained in twenty-nine of Dunlap's cases, and removed in fourteen. Stones were frequent causes of secondary symptoms. Two had reformed or overlooked stones in common duct; three had chronic pancreatitis. Function of pancreas considered—most important of digestive organs. Pancreas has external secretions, internal secretions, and metabolic action. Diabetes and glycosuria were discussed in this connection. Symptoms of other pancreatic abnormalities were given. In considering various methods of determining information on pancreatic juices, diet was classed as negative rather than positive. Fats, milk, pork, preserved fruits to be avoided; carbohydrates to be restricted. Patients appear to handle fresh fruits very well. Dunlap concluded that:

1. Simple drainage of gall-bladder more often than removal is followed by secondary symptoms.
2. Infection of biliary tract is important in etiology.
3. Chronic pancreatitis is an important factor.
4. Deficiency of external secretions of pancreas.
5. Laboratory tests for pancreatic deficiency are unreliable, to say the least. In majority of cases the physician will be forced to depend upon symptoms and therapeutic trials.

In discussion, Harris emphasized the importance of continued drainage and proper diet after operation. James called attention to ulceration of gall-bladder as a factor to be considered. Advanced inflammation of gall-bladder, when found, indicates removal of gall-bladder. Simmons related personal experience about cholecystectomy. He can take olive oil well. Suggests avoidance of long drainage for prevention of adhesions. Schoff congratulated writer of paper, and reiterated his previous statement that local men can present real papers. Reardan discussed the paper from a medical standpoint. Reported case of gall-bladder drainage followed later by operation with drainage of ducts, and later still by cholecystectomy. Two years after last operation patient was found to have amebic dysentery also. Drainage will not cure chronic gall-bladder conditions.

Hall, secretary, reported on his trip to the Hospital Convention at Pasadena, held under auspices of the League for the Conservation of Public Health, and also the meeting of the State Medical Society officers and county officers. He briefly covered the subject of the hospital meetings. Discussed at length the present political activities of the League, and asked for co-operation of the individual members of the local society in putting over the campaign against the three initiative measures at the coming election. Parkinson delivered a few pertinent remarks relative to the general apathy of individual members of the society in reference to their duty on matters of general and civic welfare. S. E. Simmons, Dufficy, and James were appointed a committee to draft resolutions on the death of Thomas J. Cox. Health Officer Hall presented a plan for a free municipal general clinic. This matter was freely discussed by many members of the Society, and upon motion by Howard the Society endorsed the clinic.

SAN BENITO COUNTY

San Benito County Medical Society (reported by C. W. Merrill, secretary)—The Society met on September 20, with six members present and one visitor. An interesting program was presented, consisting of discussion of a case of anthrax, with recovery; a case of chronic tetanus, a boy fifteen years of age, ill since June 1, but now in school; and the report of the death of an infant from inunctions of carbolated vaseline.

SAN DIEGO COUNTY

San Diego County Notes (reported by Dr. Robert Pollock)—The Medical Society has been enjoying its new place of meeting—Science Hall in Balboa Park—which has been placed at its disposal by the San Diego Museum Association. This hall comfortably seats 125, has a high ceiling, is well ventilated and heated, and has excellent acoustics. It is removed from traffic noises and adjacent to good parking space for autos; in other words, it possesses most of the requisites of a place of meeting for small scientific bodies.

The regular meeting of September 26 featured two papers, (1) Sinus Infection, by Dr. H. D. Cornell, and (2) Epidemics of Vomiting Among

Children, by Robert G. Sharp. Dr. Sharp's paper drew attention to recurring epidemics of vomiting apparently of toxic character occurring in children, and advances the treatment of temporary fasting and the administration of glucose by rectal drip method. This paper is printed in full in the San Diego Medical Bulletin of October 6.

On Saturday evening, October 7, the members of the Society were the guests of the Commander and medical staff of the new Naval Hospital in Balboa Park. The paper of the evening was an excellent presentation of the subject of prostatectomy by Arthur B. Cecil of Los Angeles. Dr. Cecil's paper covered the subject comprehensively and was supplemented by moving pictures, giving details of the operation by perineal route from the time of the preparation of the patient for the operation until the removal of the sutures some days afterwards. At the close of the program, by invitation the members adjourned to the Administration building, where an attractive luncheon had been provided, which added zest to a social hour, again attesting to the hospitality of the service men about San Diego. This hospital, opened only a few weeks ago, has four hundred beds occupied.

Paul M. Carrington announces his withdrawal from the management of the Alpine Sanatorium for the tuberculous at Alpine.

The physicians of San Diego and the entire community share in the loss sustained by St. Joseph's Hospital in the death, October 6, of Mother Superior Mary Michael, who only a few months ago celebrated her fiftieth anniversary—her Golden Jubilee of service in the Order of the Sisters of Mercy.

The Alpine Sanatorium—Dr. P. M. Carrington, who recently accepted an appointment as medical director of the Alpine Sanatorium, announces his withdrawal from all connection with that institution. Dr. Carrington assumed the medical direction of the sanatorium July 1. Since that date the Public Health Service, of which Dr. Carrington is a retired officer, entered into a contract with the sanatorium for the care of the consumptive sailors of the Merchant Marine, more than a score of whom recently were transferred there from Camp Kearny.

When asked the reason which impelled him to sever his connection, Dr. Carrington said:

"Circumstances have arisen in regard to the medical management of the Alpine Sanatorium under which I would not have full charge of all the patients. I felt that I could not continue my connection under those conditions, so have withdrawn."

Immediately following Dr. Carrington's withdrawal, four other physicians, constituting the consulting staff, also announced their withdrawal from any connection with this institution. They are Dr. H. C. Oatman, Dr. James E. Churchill, Dr. Robert Pollock, and Dr. R. de Lecaire Foster.—The Bulletin of the San Diego County Medical Society, October 6, 1922.

Staff Meeting of St. Joseph's Hospital—A special meeting of the staff was called to order by the chairman, Dr. H. C. Oatman, for the purpose of a joint meeting with the staff of the county hospital.

The regular business of the staff was dispensed; the chairman announced that a joint meeting of the two hospital staffs would give an opportunity to the visiting officers of the League of the Conservation of Public Health to discuss three bills coming before the next election—the Chiropractic bill, No. 16, the Osteopathic bill, No. 20, and the Anti-vivisection bill, No. 28.

The executive head of the hospital standardization movement, Dr. W. E. Musgrave; his assistant secretary of the State Medical Society and assistant editor of the State Journal, Dr. H. H. Johnson; the executive secretary of the League of the Conservation of Public Health, Mr. Celestine J. Sullivan; the legal advisor of the State Medical Society, Mr. Hartley Peart, and the legal advisor of the State Board of Medical Examiners, Mr. Homer Castellaw, were present. These gentlemen impressed upon the meeting the necessity of every medical man doing all in his power to defeat these bills. The outline of the propaganda was discussed and the suggestion made to follow out the program given by the League. Any amount of literature may be procured through the association's headquarters for distribution to patients and friends.

Dr. Musgrave announced that the committee would recommend that St. Joseph's Hospital and the San Diego County Hospital would be placed on the accredited list of the American Medical Association.

The chairman stated that a new St. Joseph's Hospital is to be built, commencing December 6, 1922.—Bulletin of the San Diego County Medical Society, September, 1922.

SAN FRANCISCO COUNTY

San Francisco County Medical Society (reported by LeRoy H. Briggs, secretary)—The Society and its various sections held four meetings during September. All abstracts of papers that have been received by the editor are given. The Journal will be glad to publish abstracts of 100 words or less of any paper presented to any county society.

"Some Misconceptions about Malnutrition." In discussing this subject at the meeting of September 12, Harold K. Faber stated: "Malnutrition is very commonly regarded, not only by the public, but by physicians, as the exclusive result of underfeeding. In fact, malnutrition due to underfeeding is true of only a small percentage of cases and it is related directly to diet in probably not over 40 per cent of cases. The diagnosis is up to the physician, but he should keep in mind that the medical causes are no more frequent than the social and hygienic causes. A child may be underweight because he has adenoids or tuberculosis or diabetes, but in many instances it is because he is sleeping too little or bolting his food or is worried by the conditions of his home life. These are mere illustrations of the many causes which must be looked for, but they show the sort of problem which a conscientious physician has to solve when he deals with malnutrition. Too many physicians have disregarded the danger sign of malnutrition as of too little consequence. It is a danger sign and a clue and means a lowered resistance to infection and to fatigue. The commonest misconception in this field concerns the value of height-weight standards. These standards have been attacked by laity and medical men who think that children may be normally thin, either from heredity or during periods of rapid growth. It should be clearly understood that no significance is attached by some authorities to less than 7 per cent underweight by the standard, and by others to less than 10 per cent. Such allowances will be found to take care of congenital and seasonal thinness. There is a large mass of clinical data showing that no child who is free from physical defects is 10 per cent or more under standard weight for his height, and that nearly all children 7 per cent or more underweight are suffering from physical defects or from faulty habit of hygiene or environment. Such being the facts, it is clearly the duty of every physician called upon to examine a malnourished child to make a really careful investigation of his physical condition, or his diet, of his habits and of his surroundings. He will rarely fail to discover correctible causes, the removal of which will improve the child's health and better his future."

Relief Home for Aged and Infirm—On November 21 a special election will be held in San Francisco County at which time the voters are being requested to authorize a bond issue of $2,000,000 for

the replacement of the wooden buildings now occupied by the Relief Home. The group of buildings constituting the Relief Home house over 1000 people.

St. Joseph's Hospital Staff Active—W. T. Cummins, director of the department of pathology and laboratories, addressed the hospital staff on September 20 on "The Value of the Chemical Laboratory." This department is increasing in importance and now has two technicians, a Sister and Miss Dora Dasenbrock, and another Sister statistician.

Others who spoke at the September meeting were: William Quinn, on "Suppurative Appendicitis"; R. F. Grant, on "The Ochsner Treatment," and David Stafford, on "Gastric Ulcer."

At the October meeting A. S. Musante spoke on "Surgical Centers of the East," touching on observations made in a two months' tour, and urging that annual clinics at the local teaching hospitals be held, starting next year. Case records were presented by Otto Laist on "Mediastinal Tumor," and R. H. Berndt, on "Pyelitis."

William Reilly was elected vice-president of the staff and J. M. Stowell and D. D. Stafford were appointed on the executive board.

On November 15 H. A. Ryfkogel will talk on "The Diagnosis of the Acute Inflammation of the Abdomen."

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by A. C. Soper, secretary)—The September meeting was held at the Cottage Hospital with President Mellinger in the chair. Fourteen members and one candidate for membership were present. Dr. Koetter presented a case of hypopituitarism. "Retention Products in the Blood," with special reference to the urological features, was discussed by George F. Farnam. "Effect of Radiation on the Flora of the Tonsils" was the subject of a paper by H. J. Ullman, who discussed the relative values of radiation and surgery in this connection.

SANTA CLARA COUNTY

Hospitals, Clinics and Laboratories (reported by Dr. E. P. Cook, secretary of Santa Clara County Medical Society)—

San Jose Hospital, San Jose.
Columbia Hospital, Inc., East San Jose.
O'Connor's Sanitarium, San Jose.
Santa Clara County Hospital, San Jose.
County Hospital Clinic, San Jose.
Good Cheer Clinic, San Jose.
X-Ray Laboratory of Dr. Richards and Dr. Bullitt, San Jose.
Associated Radiograph Laboratories, San Jose.
Finley M. Eastman, Pathologist, San Jose.
Petry Sanitarium, Mountain View.
Palo Alto Hospital, Palo Alto.
Palo Alto Hospital X-ray Laboratory, Palo Alto.
The Gilroy Private Hospital, Gilroy.
The Children's Clinic, Gilroy.
X-ray of Dr. Elmer Chesbro, Dr. J. A. Clark, Gilroy.
The Good Cheer Clinic, Los Gatos.

YOLO COUNTY

Hospitals, Clinics and Laboratories (reported by Dr. Lela J. Beebe, secretary Yolo County Medical Society).

Yolo County Hospital, Woodland, 60 beds; Warden, L. H. Savage; county physician and medical director, Dr. H. D. Lawhead.

Woodland Sanitorium, Woodland, 47 beds; medical director, Dr. F. R. Fairchild; business manager, H. O. Cummings.

X-ray Laboratory at Woodland Sanitorium; radiography and radiotherapy, radium therapy also.

Children's Health Conferences at Woodland Sanitorium, infant and pre-school group, once weekly; school children, once weekly.

THE UNITED STATES SUPREME COURT AND CHIROPRACTORS

The United States Supreme Court decision which upheld the Medical Practice law of the State of Ohio requiring chiropractors, sanipractors and other drugless healers to be licensed, was met with the statement through the president of the Chiropractors' Association that they, the chiropractors, would "rot in jail" before the law would be obeyed.

It would seem that if these chiropractors, sanipractors and other drugless healers felt that their education would stand the test of investigation they would welcome regulation rather than oppose the state licensing boards.

The opinion of the United States Supreme Court was written by Justice Wanamaker in such forceful style as to make it a valuable contribution to health literature. The following quotation is an indication of the splendid material contained in this decision:

"Public health is the very heart of public happiness. The constitutional guarantees of life, liberty, and the pursuit of happiness are of little avail, unless there be clearly implied therefrom the further guarantee of safeguarding the public health, in order that life, liberty and the pursuit of happiness shall be made practical and plenary."

The court unquestionably was familiar with his subject and based his decision not only on knowledge of what should be required before authorizing the practice of any system of the healing art, but as well on the dictates of common sense when he said:

"It is surely only elementary to say that before one can treat a disease intelligently, he must know how much about the nature and extent of that disease, the organs and parts affected, and even the cause of that disease. The state should set its standards high, so as to abundantly protect the public from the mistaken ignorance, however well intended, from charlatanism, from professional quackery, however garbed in alluring advertisements, and from all those who would prostitute their profession to a profiteering basis. Manifestly before this scientific knowledge of the human body can be properly acquired, there must be some preliminary educational qualifications of a general nature. . . . It is absurd for anyone to say that you can develop and train a mere hodcarrier with comparatively no education to become a skilled physician or surgeon in the same time that you can a college man with the same natural endowments."

The court disagreed with the argument that chiropractic treatments were not harmful and that it should not be necessary for chiropractors to study and be examined in subjects not directly connected with the practice of medicine, which contention he answers in no uncertain terms by saying: "To say that such knowledge in no way pertains to the treatment of the chiropractor is sheerest nonsense, even to a layman."

In the last analysis, all residents are wards of the state. Taxes are paid, administrative officers are supported, departments organized to safeguard our homes and our lives that we may prosper. A community progresses only as the health of its people is advanced. The State, therefore, exercises a legitimate right in taking a forceful stand for the protection of health, the preservation of life and for the advancement of the standard of its citizenship. —Information Bureau, State Board of Medical Examiners.

BOOK REVIEWS

History and Bibliology of Anatomic Illustration in its relation to anatomic science and the graphic arts. By Ludwig Choulant. Translated and edited with notes and a bibliography by Mortimer Frank, B.S., M.D., 435 pages. Illustrated. Chicago: University of Chicago Press. 1920.

A beautiful translation of Choulant's book illustrated with many wonderful drawings of the ancient anatomists. The drawings of great artists, da Vinci, Rubens and others of their time who considered the human body less as a dissected specimen than as a living and moving handiwork of Nature, will make this work a delight to those who long for an occasional holiday from our card-catalogued and matter-of-fact surroundings.

L. E.

Life of Jacob Henle. By Victor Robinson. New York: Medical Life Company. 1920.

An interesting, rather sketchy, account of the life of Henle and his friends. As Henle had the faculty of making sincere and lasting friendships, there is about as much space devoted to the latter as to the former.

The book furnishes an hour or two of pleasant reading, and may serve to stimulate the interested to a more extended study of the life of one who is remembered now as an anatomist whose name is associated with several structures.

Whereas his early life had its share of romance, ranging from imprisonment to educating a serving maid to take her position as his wife, his later years were passed in the quiet of Gottingen in the midst of a devoted family and friends.

The last chapter, dealing with the contributions to science, though containing all the material, might be improved by an appended bibliography.

A. L. F.

Hayfever and Asthma—care, prevention and treatment. By William Scheppergrell, A. M., M. D. 274 pages. Illustrated with 107 engravings and 1 colored plate. Philadelphia and New York: Lea and Febiger. 1922. Price, $2.75.

The book is a concise treatise on the relation of hayfever to wind-borne pollens by one who has done much original work in this field. It should serve as a reference book for anyone treating hayfever. There are several tables giving the most frequently met hayfever plants in each State and their approximate dates of pollenation. Many illuminating points, not heretofore generally known, are brought to the reader's notice. The book is recommended to anyone interested in this malady, which affects about one per cent of our population.

J. M. R.

BOOKS RECEIVED

Ophthalmoscopy, Retinoscopy, and Refraction. By W. A. Fisher, M.D., Chicago, Professor of Ophthalmology, Chicago Eye, Ear, Nose, and Throat College; late Professor of Clinical Ophthalmology, University of Illinois. 248 illustrations. Published by W. A. Fisher, M. D., 31 North State Street, Chicago, Ill.

Physiology and Biochemistry in Modern Medicine. By J. J. R. MacLeod, M. B., Professor of Physiology in the University of Toronto; formerly Professor of Physiology in the Western Reserve University, Cleveland, Ohio. Assisted by Roy G. Pearce, A. C. Redfield, and N. B. Taylor and by others. Fourth edition. 243 illustrations, including nine plates in color. St. Louis, C. V. Mosby Company, 1922.

Physical Diagnosis. By W. D. Rose, M. D., Lecturer on Physical Diagnosis and Associate Professor of Medicine in the University of Arkansas. Third edition. 319 illustrations. St. Louis, C. V. Mosby Company, 1922.

The Elements of Scientific Psychology. By Knight Dunlap, Professor of Experimental Psychology in The Johns Hopkins University, Baltimore. Illustrated. St. Louis, C. V. Mosby Company, 1922.

Socialistic Tendencies in Medicine—In recent years, under cover of promoting the welfare of society or of some part of it, James A. Gardner, Buffalo (Journal A. M. A., August 12, 1922), states that many so-called reforms have been inaugurated which, in reality, are little more than the outcome of the emotional desires of restless faddists or of the ideas of extreme and radical discontents. The contention is sane that all reforms of whatever nature should be made only after patient and scientific investigation of the causes and the cure of the evil sought to be corrected, and that the desire to bring about such reforms presupposes knowledge obtained by serious investigation and careful research, unhampered by emotion or prejudice. The field of medicine has been a fertile one for the agitator and the propagandist. Reformers and uplifters have been allowed to invade, unopposed, the practice of medicine and surgery, until the time has arrived for raising the danger signals. The peril of the situation becomes more urgent when it is realized that the public is being educated to believe that the socialization of the medical profession will bring higher standards of health. The fact is that, with the initiative and individuality of the physician removed, the profession will cease to attract to it men of energy, ability and ambition, who are now keeping American medicine in the front rank of intellectual and scientific achievement. Prevention and education need the aid of the Government; but the State should not compete with individual skill and superior knowledge and efficiency in the care of those who have money to pay, and so should not be treated at public expense. Public health is the musical instrument easiest for the welfare worker to play, and the softest chord is the venereal problem. It is not wise for a State to pauperize its people, nor is it fair to the medical profession to deprive it of its legitimate livelihood. The physician has always been too busy looking after the needs of his patients to give much time to his own interest. Unless he awakens to the drift of the tide, there will soon be little inducement for a young man of real ability to enter the medical profession. The field of social welfare or social reform has developed to such an extent in recent years that it is now a recognized profession, remunerative and popular. The solution of this problem is suggested by Gardner under three heads: (1) There should be a social service, ably trained to make real and thorough investigations and competent to distinguish between the needy poor and those possessing the ability to pay. (2) There should be an awakening of the medical profession to the realization that it is equally responsible for this pauperization. There should be censorship of the services of the physician by some responsible body like the county medical society, as has been done in contract practice, so that patients able to pay should not be cared for gratuitously. (3) There should be education of the public to an understanding that if the standards of medicine are lowered through the loss of impetus and initiative in the young physician, the public will be the chief sufferer.

BUSINESS AND THE BUSY PHYSICIAN

Why not let our advertisers help you?

ABOUT THIS DEPARTMENT OF THE JOURNAL

The department of medical economics or the business of medicine was started in the Journal to touch lightly upon matters of organization and the business side of medicine. There is now one medical journal and several hospital journals devoting all of their space to this subject, and many other medical journals include occasional articles at various times.

We had in mind also to follow the usual custom and call attention to the offerings of our advertisers. Advertisements are the principal source of income of any publication. We can increase the usefulness of the Journal only by increasing the extent of its advertising. The Journal in its present size and form costs about $20,000 a year. Its income from advertising is now paying all of this expense.

In addition to this feature, the department has developed into a service, with specific inquiries about specific subjects from members in all parts of the State. The editor and other officers of the State society do not feel themselves competent to give financial advice, but reliable banks, trust companies, bond houses and insurance companies who are experts in financial matters are advertisers in the Journal. We believe they are interested in the welfare of the medical profession, and that they will give conscientious advice courteously and with pleasure to members of our organization. This number contains the advertisements of the Union Trust Company; San Francisco Savings and Loan Society; Anglo-California Trust Company; E. H. Rollins & Sons; Pacific Mutual Life Insurance Company.

Doctors and Investments—"The reason most doctors have so little money to invest in profitable ways is because they waste so much in 'wild cat' schemes. The doctor is the exemplification of the 'hayseed,' so dear to the heart of the bunco-man. It was estimated that more than a million dollars went out of a city of about forty thousand people, in the Southwest, in the Texas oil fields, in 1920—never to return. It is known certainly that at least fifty thousand dollars of this came out of the pockets of the doctors of that city. This against the advice of bankers and all well-informed and reputable financial representatives.

"In contrast, a doctor is known to us who says that he never invests in anything except bonds of banks or those recommended by reputable banks; this doctor recently retired from practice, at the age of forty-five, with sufficient income to support himself and wife for life.

"The lesson is plain. When you invest, know what you are purchasing. If you wish to gamble, play the races or sit in a poker game, losing what you can afford to lose. Your money to be invested can be invested safely. If you do not know the risks in a proposed investment, inquire of a reputable investment concern, who will give you the facts."—Editorial, Southern Medicine, October, 1922.

Insurance and Taxes—"I have come to the distinct conclusion that by far the best and, indeed, almost the only practical way of guarding against the possible ruinous loss by a forced sale of securities for the purpose of paying the various estate and inheritance taxes that are being imposed nowadays, both by the National and State Governments, is by means of life insurance which, for a moderate annual payment, will insure the sum necessary to pay such taxes without the sacrifice of the securities."—Elihu Root.

Life Insurance Examiners—There are life insurance companies doing business in California who place all of their medical work in the hands of members of the State Medical Society. There are others who do not.

MEDICINE IN THE PUBLIC PRESS

The public press is showing a constantly increasing interest in matters of public health, medical education and the practice of medicine. Whatever the opinion of physicians as to the quality of most of this publicity, we cannot fail to appreciate its far-reaching influence in molding public opinion and thus determining, in a measurable degree, medical progress. Some of the articles are along the right lines, but the vast majority are thinly veiled propaganda of the socialistic organizations, or they are promoting some selfish interest. It is believed that the attention of the readers of the Journal should be called to some of this literature with appropriate comments as to its real significance and possible influence. This will be done in this department from time to time.

Better Health Service—The articles from this service now appearing daily in the "San Francisco Examiner," the "Los Angeles Examiner," the "Seattle Post-Intelligencer' and shortly to appear in other papers, is the best example of the best method of enlightening the public upon questions of preventing and treating disease that has yet been devised. This service, which is furnished by the League for the Conservation of Public Health, is the only one anywhere that is supplied, edited and controlled by an organization of physicians. The articles are prepared by physicians, edited by a board of physicians and put out in the name of an organization of physicians. These articles now reach over one million readers and the possibilities for further development of the service are only limited by the interest of physicians in supplying interesting and instructive material presented in an attractive and accurate manner. If you are genuinely interested in making public enlightenment a fact and not a theory send in your articles.

Education by Correspondence—In answer to questions regarding the so-called American University and the teaching of medicine, nursing and similar professions by mail, we quote from a recent number of the New York State Journal of Medicine:

". . . Even our government postal department seems to find it impossible to stop the so-called extension courses of the so-called American University which under various names from a little suite in an office building in Chicago, with never a resident student so far as we can learn, has, for many years, conducted a profitable advertising business through the mails wherever English is spoken. Correspondence courses in Mechano-therapy, Suggestive-therapy, Spondylo-therapy Chiropractic, Osteopathy, Bust development, get-the-coin-therapy, with 'handsome diploma' are given for a scale of fee sliding from two hundred dollars down to whatever the victim can be induced to give. Thirteen years ago London Truth said: 'It passes my understanding how wealthy newspaper proprietors . . . can condescend to take money for foisting this sort of bunkum on their readers, but as long as they do so, cheap postage to America will certainly put money into some pockets,' and in describing the 'college' calls it 'a concern which proposes to give postal tuition in quackery to British fools.' The American Medical

Association Journal says: 'A description which can only be improved by the substitution of "English-speaking" for British!' When we saw the advertisement from the Police Gazette of July 1, 1922, that 'any one' could be taught, by correspondence from the 'American University' to become 'a doctor,' to earn 'from $3000 to $5000 yearly,' and to become 'a member of an honorable and respected profession,' we were shocked, both because we had not seen the seductive pink sheet very often since our country barber shop days, and because we had believed that such advertising violated our postal laws and had been suppressed. We are now convinced that it will go on as long as there are minute men, and one is born every minute, to respond to its call."

The Series of Articles Running in "Hearst's International Magazine"—This magazine is publishing a series of articles by Paul H. De Kruif which ought to be read by every physician because they are being widely read by thousands of other persons. Dr. De Kruif is publishing some unpleasant truths about the prevention and cure of disease and he is saying some things that most physicians will resent as being inaccurate and destructively critical rather than constructive. Norman Hapgood in the September number of "Hearst's International," which contains De Kruif's first article, says, editorially, regarding these articles:

"The doctor is present at birth and at death. He comes when the life of a dear child lies in the balance, and he consults with us about the recurrent headache. The difference in the home between an able family doctor and a quack (or semi-quack) may be a difference in happiness beyond estimate.

"The series, to which we publish this month the introduction, is of no use to those who wish the name of some pill, or some new medical nickname, by resort to which magic relief can be brought to heart-disease and hiccoughs, to erysipelas and earache, to corns and constipation. It is of no value to a fool. To those, however, who realize that the choice of a doctor is one of the most important of acts, and that medicine has exact technical bases, the series is indispensable.

"He who reads with a trifle better than moron attention the expert and varied articles in the series will see emerging clearly the principles that should guide an intelligent person through the maze of medicines and the delirium of fake doctors. Never have medicines been so many; of this multitude only a few mean anything. It is easy to know which ones are real.

"Among those who will gain most are earnest doctors, not themselves living in an atmosphere of research, who will be grateful to be shown how they also have fallen victims in a false drug traffic.

"Indeed, one of the ironies of this story is that what appears as progress sometimes is merely the new form of an old idea. In the brilliant campaign of fifteen years or so ago in which Samuel Hopkins Adams published his articles on 'The Great American Fraud,' there was dealt to the patent medicines a blow from which the effect remains. Selling to the public carbolic acid and water as a cure for consumption, carditis and cramps is not as easy as it was. But newer and subtler methods of fraud have taken the place of the earlier, cruder forms. The foremost frauds are now 'ethical.' That means they are advertised not direct to the public but in the medical press. Which makes this continued story a new tale, sad at once and diverting."

The second article of this series, in the October number, is devoted to the Vitamin Craze. If we judge reaction correctly the Vitamin Craze is already on the wane and we doubt very much whether De Kruif is doing more in this second article than tying the usual tin can to the dog's tail.

California Also—We still receive newspaper clippings from Elwood indicating that the name of one of the doctors there, president of the county medical society, appears in the daily papers every day or so in connection with a report of medical and surgical cases, and we have been asked by other doctors, "What is the State Medical Association going to do about it?" As a matter of fact, the State Medical Association will do nothing about it, for each county medical society is the judge as to the qualifications of its members, and not only approves but censors the conduct of its members. If the county medical society is satisfied that one of its members is so guilty of unprofessional conduct that he should be punished for the offense, then it is up to that county medical society to bring the offending member before the society to answer charges and receive such sentence as the majority of the members of the society may think indicated after the facts have been presented and properly analyzed.—Indiana Medical Journal, September 15, 1922.

Pauperizing Practices—The Physicians' Protective Association of Buffalo, made up of 450 of the 857 physicians in that city, is carrying on an energetic fight against the pauperization of the public through free medical services in local hospitals. Abuses are tolerated under the mask of public health, and the Buffalo physicians believe that it is time to put a stop to the practice of making dependents and paupers of people who are able to pay something for the services rendered. The question concerns the public more than it does the medical profession, for no community can afford to tolerate widespread and unnecessary pauperization of any kind of unnecessary free aid.—Indiana Medical Journal, September 15, 1922.

OBITUARY

WILLIAM STEWART HALSTED

With the death of Professor Halsted, surgery lost one of its great leaders. This philosopher-surgeon was ever intent on extending the bounds of medical knowledge, and devoted himself whole-heartedly to qualifying and enriching the minds of his many pupils. We are grateful for this legacy, which he so bountifully distributed during his lifetime, "teaching what he had learned, and learning in order that he might teach."

We glory in his tireless energy, his quiet, simple and unostentatious manner, and in the splendid accomplishment of his many tasks. He was truly a great man, a daring and brilliant pioneer of surgery, and his single-hearted and self-sacrificing devotion to the cause of scientific research had its reward in achievements of the most vital and far-reaching nature.

DEATHS

MacAulay, Sarah Hatton. Died at Monterey, Calif., Sept. 17, 1922. She was a graduate of Hahnemann Med. Coll. of the Pacific, 1904. Wife of Dr. Martin MacAulay.

Cross, Harry N. Died August 18, 1922, aged 55. Graduate of Cooper Medical College, 1889. Member of San Joaquin County Medical Society.

Merryman, Thomas J. Died at Whittier, August 21, 1922, aged 77. Graduate of Hahnemann Med. Coll. and Hosp. of Chicago, 1868.

ORIGINAL ARTICLES

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

The author of an article appearing in the JOURNAL *is entirely responsible for all statements and conclusions. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the language and method of presenting their subjects. All manuscripts will be carefully read, but editorial privileges will be exercised only to a very limited extent. It is believed that the manner of presentation of any subject by any author determines to no small degree the value of his conclusions. Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented by the author as little disturbed as possible by the editors. However, the right to reduce or reject any article is always reserved.*

SPEECH DEVELOPMENT IN ORTHOPAEDIC CASES *

By CHARLES G. STIVERS, M. D., Los Angeles, Calif.

The modern conception of orthopaedics, the development of perfect children, is far removed from the old idea of the correction of club-feet and other gross deformities. I have been associated with a group of orthopaedic surgeons for several years working out problems that presented themselves. One of these was the development of the language faculty, not only for its use as a means of expression, but also as one of the psychomotor trainings. It has been discovered that speech and language drill exercise the faculties of inhibition, concentration and attention, memory, co-ordination and other faculties by reason of the psychological precept, that the exercising of one mental faculty through association develops others and is a useful part of the general orthopaedic supervision of a crippled child.

The long period of convalescence after operation while wearing casts and braces need not be a period of mental inactivity. On the contrary, this period is utilized by us to develop the mental as well as the physical body. I have published elsewhere ("Systematic Training in the Treatment of Inco-ordinations, Especially of Speech") a comprehensive study of all the psychological factors entering into this subject and it is not necessary to go into that phase fully here. Suffice it to say that our procedures are founded upon sound psychology, and as we advance in the work, confirmation of our expectations is evidenced by improvement in both the mental and the physical bodies. A recent study of the voice and speech among the crippled children admitted to the Orthopaedic Hospital-School of Los Angeles in the four years from 1918 to 1921, inclusive, revealed the fact that nearly 10 per cent also had some speech defect.

It is a clinical fact that defectives usually show more than one deficiency. A large proportion of physically handicapped children show the tendency to two or more departures from the normal; for instance, there is often a cleft palate with a hare lip or a spina bifida or extra fingers or toes or extrophy of the bladder, club-feet and other physical handicaps often occur in children of subnormal mentality, etc. We are not surprised, therefore, to find a large proportion of the physically handicapped with speech defects.

Remember that motor areas control leg, arm, fingers, tongue, lips and cheeks, all parts of the expressional, gestural and motor faculties. We can easily comprehend how injuries to the head at birth could traumatize any part of this motor area and be followed by a failure to develop vocal expression, a motor as well as sensory faculty, besides various paralyses of the arms and legs. In general terms any pathological process whether inflammation (intracranial or intraspinal) at or after birth or traumatism resulting in actual loss of nerve substance, the formation of cysts, cicatricial bands or pacchy-meningitis destroying the integrity of the motor or sensory areas of the brain, including those governing speech, may result either in lack of sensory perception of the spoken or written word or failure to develop speech either written or spoken or both.

Speech supposes co-ordination; if brain areas governing balance, rhythm, orientation, time and space preception are injured then speech development and production will suffer.

Defective speech development or production is found most commonly in cerebral spastic palsy, inco-ordinations, ataxias, cerebro-spinal inflammation and in mentally subnormal children. In these cases treated at the Orthopaedic Hospital-School it has been a fundamental principle of treatment that the speech education or development or drill was an essential part of the treat-

* Read before the California State Medical Association, May 17, 1922, at Yosemite Park, in connection with the film, "Development of Speech in Orthopaedic Cases."

ment of a general motor paralysis. In cases of paralysis of the arms and legs, speech drill is considered to have a beneficial action through association fibers reaching other brain centers. A spastic paralysis child of 2 to 10 years of age with hyper-acting arms and legs, drooling saliva constantly, whose muscular and nervous system is filled with fatigue toxins, should first of all have the endocrine balance investigated and suitable medication and diet prescribed. Rest is of the utmost importance and to secure it the arms and legs are placed in casts or braces after such operations as may be decided upon to secure motor function in the future.

I found in a recent study of all the admissions to the Orthopaedic Hospital-School in Los Angeles during 1918-19-20-21 that out of the 1044 cases there were eighty-two cases with a speech defect in addition to their orthopaedic troubles. These cases were found in spastics, inco-ordinations, ataxias, polio-encephalitis and faulty postures. Normal children of school age show from 1 to 2 per cent of speech defects (Gutzman and others). Crippled children of Los Angeles showed nearly 8 per cent of speech defects, an example of the well-known fact that individuals with one developmental defect, in the motor or expressional system, are apt to show other defects; for example, cleft palate, hare lip, etc.

Birth injuries resulting in motor paralysis of one or all of the limbs often include damage to the motor speech centers in the cortex and probably to the central nuclei, the caudate lenticular and red and optic thalami with disturbance of co-ordination and rhythm in the speech mechanism.

Remembering that speech is motorized thought and that gesture is the primitive speech racially, we realize how impossible it is for a case of muscular inco-ordination or paralysis of the arms and legs to develop that stage of seemingly purposeless muscular activity with cooing and babbling that comes about the seventh to twelfth month or just previous to the development of the spoken word. The crippled child probably cannot lay the foundation for gestures or spoken words or written speech (O'Shea — "Linguistic Development and Education").

In health every muscle movement is registered in the muscle memory centers of the brain. Muscle movements spring from previously registered memories and no voluntary or conscious muscle effort is conceivable without the aid of this already stored memory (Goddard). Normal children (non-cripples) with normal motor ability, have placed in their brains through countless repetitions an adequate supply of perfect muscle memories. These can be used at will for perfect speech or gesture or for walking or dancing or performing any other motor acts.

The paralyzed or inco-ordinating or spastic child or one with some grave nervous degeneration affecting the motor apparatus, who has uncontrolled, hyper-acting gestures or motor function or no purposive movements or no speech or imperfect speech, has of necessity stored in his brain by these imperfect muscular acts, only imperfect muscle memories. Muscles are not simply means of moving bones and joints, but are living, moving impression centers from which come many of our most valuable lessons concerning the external world. Speech in a non-crippled child develops after a cooing, seemingly purposeless, bilateral movement period. In crippled children there may be no such pre-speech period and when the child's desire for expression has grown to a point where it demands motion or action, there are no trained co-ordinated memories stored ready for utilization as the foundation of the spoken word.

The development of speech in crippled children where speech does not exist is a problem to be approached by the entire staff of an orthopaedic hospital.

The child of whatever age is put through a most searching examination as to diet, habits, measurements, etc. The orthopaedic surgeons correct the faulty conditions that can be remedied by various operations followed by casts, braces and appliances. In the spastic child as soon as it begins to develop quietness, when the hyper-acting arms and legs are calmed, the speech drill is begun. This is carried on at the same time as the general muscular exercises and usually in a reclining position. Breathing exercises, vowel sounds, counting, and one syllable words with games, simple bright colored objects, pictures (cut out of magazines and books) of animals and familiar objects, keeping everything well within the comprehension of the child, with arm movements are used. The arm and leg exercises follow a definite plan of using groups of muscles opposed to those that are hyper-acting or contracted. In a spastic with a tendency to adduction and inward rotation, the movements are outward, upward and backward.

In cases of inco-ordination listening to music, beating time, reciting rhymes and games (bean porridge hot, etc.) is used.

The language ability is stressed at all times by making the exercise a form of game in all cases except those with hyper-acting muscular systems (spastics). All excitement is avoided in these cases.

Speech training alone as a biological necessity in the utilization of muscular co-ordination to express emotion, does several definite things for crippled children:

First, it correlates muscular activity with mental images in the expression of emotion.

Second, it develops association paths in the brain.

Third, it increases breathing power, with more oxygen, better blood and better voice.

Fourth, it develops control (inhibition) of the purposeless, energy-wasting muscular movements.

Fifth, it strengthens and co-ordinates muscles of the tongue and cheeks and assists in the cure of drooling.

Sixth, linking gesture and other motor expressions of emotion to speech drill, improves the nutrition and strength of all the muscle systems used in the exercises.

(406 Auditorium Bldg., Los Angeles.)

FURTHER EXPERIENCES IN SACRAL ANESTHESIA IN UROLOGY *

By ALBERT J. SCHOLL, Jr., M. D.
Fellow in Urology
The Mayo Foundation, Rochester, Minnesota

The anatomic structure of the sacrum, in which all the lateral foramina communicate with the main central canal, favors the distribution of fluid introduced through any of the openings. The sacrum is covered only by a thin layer of subcutaneous tissue and the openings are readily located by means of prominent landmarks and in most cases are easily entered.

There are two common methods of anesthetizing the sacral nerves, one by merely injecting novocain solution into the main central canal through the caudal foramen, and the other by individual injection of each nerve as it leaves the lateral sacral foramen. The caudal injection is satisfactory for most operations on the perineum or external genitalia, and for practically all endovesical procedures. After making a single caudal injection it is necessary to wait twenty minutes before complete anesthesia occurs. It has the further disadvantage of failing to induce complete anesthesia in from 10 to 15 per cent of the cases. If the lateral nerves are injected individually there is an almost immediate anesthesia of the area involved and failures are unusual. It is much more difficult to inject the nerves as they leave the canal than to make the single caudal injection, and the contact of the needle against the periosteum, or the occasional striking of the nerve, causes the patient pain.

Both methods of injection are best carried out with the patient lying on his abdomen. The caudal injection is a suitable office procedure; it incapacitates the patient only during the period of the examination, and is generally not suited for extensive cutting operations. The anesthesia varies in duration; the period of maximal intensity in most cases is about sixty minutes. The patient is placed on the table face downward, the dorsal and lumbar spine is slightly elevated above the sacrum so that the injected fluid will remain in the region of the sacral nerves. The sacral hiatus is located at the lower end of the sacrum as an elastic depression at the sacrococcygeal joint. In most cases it is triangular in shape; the lower two angles are bounded by the cornu of the incompletely fused fifth sacral vertebra. The skin is anesthetized over the ligament, a thin spinal needle held at right angles to the skin is then inserted through the skin and ligaments (Fig. 1). A definite crunch is felt as the needle passes through the ligament. The point of the needle is then directed up the canal which it should enter readily. The needle may strike the lateral wall or the point may become buried beneath the periosteum; slight withdrawal and redirection of the point will in most cases permit insertion for a sufficient distance, about two to four cm. It is possible to enter most canals, although occasionally an ossified membrane is encountered. In some instances the canal cannot be located, or the anterior posterior diameter is too small to permit the entrance of the needle. Not infrequently the needle enters one of the sacral veins and on withdrawal of the stylet a few drops of blood appear. The needle should then be partially withdrawn and the point redirected. If blood flows freely from the needle, the injection should be abandoned; if a portion of the injected solution is absorbed through a tear or large puncture in the vein, symptoms of toxemia are likely to appear immediately and the resulting anesthesia will be unsatisfactory.

There is always the possibility that the needle will enter the dural sac, and this will be indicated by the appearance of spinal fluid when the stylet is withdrawn from the needle (Figs. 2 and 3). The needle is generally inserted only two or three cm. and it is only in the exceptional case that

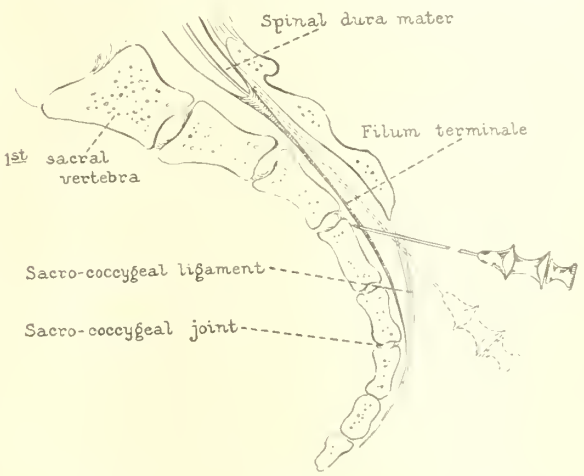

Fig. 1
Section through sacrum, showing relation of needle to sacral canal and dural sac.

the dural sac reaches to within four or five cm. of the sacral ligament. In one case the dural sac was punctured after the needle had entered the canal only two cm. If spinal fluid appears, the needle should be withdrawn until the flow stops before the injection is made.

Novocain solution is prepared fresh for each case. Thirty cubic centimeters of a 2 per cent solution of novocain bicarbonate solution is used in most cases. In children, or in adults with reduced vitality, the dose is diminished. The most satisfactory results have been obtained from Metz novocain; it is kept in powders with enough soda bicarbonate to make 30 cc. of a 2 per cent solution; sodium bicarbonate 0.15 gm., sodium chloride 0.1 gm., and novocain 0.6 gm. The powders will remain fresh for from ten to twelve days, after which they lose strength, and when injected may cause mild symptoms of toxemia. As suggested by Brock of the Mayo Foundation, if the novocain is kept separated from the bicarbonate until ready for use the powders do not deteriorate so readily.

The addition of sodium bicarbonate to novocain gives a solution which diffuses more readily through the nerve sheaths; the anesthesia is generally of a greater intensity, and the possibility of

* Presented before the California State Medical Society, Yosemite Valley, May, 1922.

a failure is less than when novocain alone is used. The powder is dropped into 30 cc. of boiling distilled water and the solution removed from the flame. After the solution cools several drops of 1:1000 epinephrin are added. In certain cases the epinephrin produces a mild reaction; the patient complains of a feeling of suffocation and increased heart action. On this account only small amounts of epinephrin are added. The solution should be injected slowly, three or four minutes being taken for the injection of 33 cc. The fluid should meet with little resistance; if force is required, the needle probably is not in the open sacral canal and should be readjusted. After the injection the patient assumes the sitting posture in order to retain the fluid in the sacrum. Anesthesia of the sacral nerves first appears in about ten minutes and reaches its maximal intensity in from twenty to thirty minutes.

Caudal injections, similar to spinal anesthesia, give complete relaxation of the structures supplied by sacral nerves. There is paralysis of the reflex arc, causing muscular relaxation that is greater than can be obtained with general anesthesia; at the same time the co-operation of the patient may be obtained. Sacral anesthesia differs from spinal anesthesia in not necessitating hospitalization of the patient; the risk attached to local blocking is practically nil, and is not followed by the undesirable after-effects which so often accompany spinal anesthesia.

Caudal injections give very satisfactory anesthesias for urologic examinations and treatment. The wall of the bladder is completely relaxed and the bladder thus distended. Such relaxation with absence of pain and straining, permits the operator to carry out a thorough, unhurried examination of the bladder and ureters. In none of the patients examined in this manner in the Mayo Clinic have there been undesirable after-effects. The injection may be repeated if necessary. In certain types of cases, such as severe cystitis and pyelonephritis, caudal injections have been given in order to facilitate lavage of the renal pelvis. In one case ten injections were given in seven weeks. The reaction following cystoscopy in severe cases of cystitis is not uncommonly due to voluntary muscle spasm around the cystoscope, especially in the region of the neck of the bladder; this does not occur after sacral anesthesia. In a number of patients with pyelonephritis and severe cystitis who were given periodic renal lavage, treatments were first carried out under caudal anesthesia and later merely with urethral cocainization, the convalescence in these cases was invariably much smoother and easier when caudal anesthesia was used. In several instances, patients refused to submit to cystoscopy without caudal anesthesia.

DISCUSSION

Failures result from various causes. In some patients it is impossible to enter the canal; this generally occurs in patients with small sacrums, in those with marked hypertrophic arthritis, or with old traumatically distorted pelves. Traumatic distortions of the sacrum are not uncommonly seen in conjunction with old traumatic urethral strictures. Patients with occult spina bifida often have deformed sacral foramina and even if the canal is entered the anesthesia may be deficient. In certain cases of malignancy of the bladder there is an extension of the growth through the wall of the bladder to outside structures not anesthetized by the sacral nerves. In one case failure resulted from an extension of the growth into the sacrum which blocked the sacral canal. The majority of failures are due to errors in technic, or to poor solutions. Four of the failures in this series occurred on the same day and were due to the use of old powders.

Caudal anesthesia is very satisfactory for the examination of infected bladders. Tuberculous bladders which hold only 20 or 30 c. c. of fluid may be distended sufficiently to permit complete examination with catheterization of the ureters without discomfort to the patient.

In malignant bladders a thorough examination of the growth, with the removal of a specimen for histologic study, may be carried out. The growth may be extensively fulgurated over a long period, or radium may be planted in the growth without the patient being aware of the manipulation.

In the cases of litholopaxy a number of patients had large stones removed which required more than an hour of crushing and washing.

One of the most satisfactory features of caudal anesthesia is its almost complete absence of postoperative sequelae. Several patients complained of

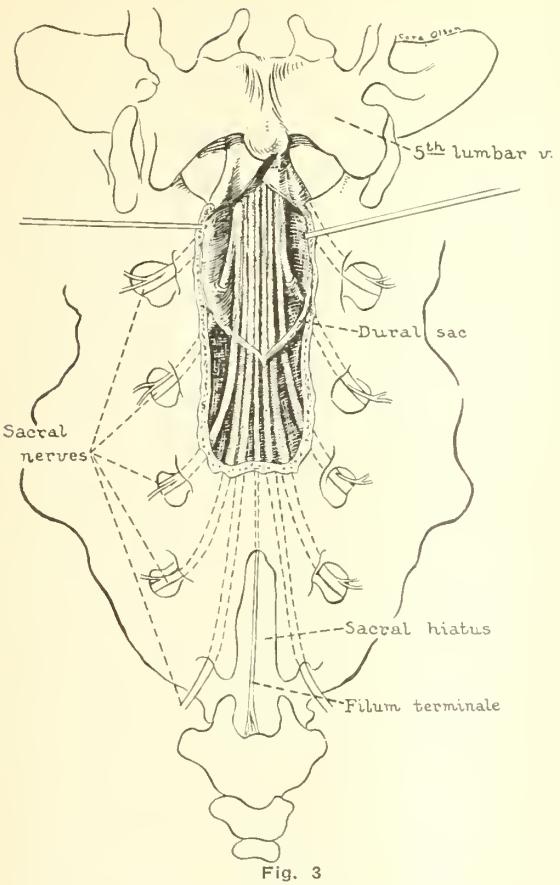

Fig. 3
Showing relation of dural sac to the sacral canal, nerves and sacral ligament

nausea and two lost consciousness for several minutes. One patient developed a definite psychosis following the injection which lasted about thirty minutes. Transient sensations of faintness and forceful and increased heart beat were occasionally seen. In no case were delayed or prolonged after-effects observed, and in none was there indication of paralysis of the anesthetized nerves after the general effects of the anesthesia had receded.

Caudal anesthesia gives an excellent relaxation of the lower ureter, and permits the manipulation of ureteral stone; in some cases several large ureteral catheters may be readily inserted to the site of the stone without causing the patient discomfort. Occasionally there is relaxation of the lower ureteral segment and spasm of the upper ureter which causes an impassable angulation.

Sacral anesthesia is simply and easily carried out. It causes very little discomfort to the patient, gives a satisfactory working anesthesia, and rarely produces undesirable after-effects.

Provisions of Sheppard-Towner Act Rejected by Five States—"During the summer the State of Maine, through the action of Governor Baxter and his Council, and the State of Louisiana, through the action of its Legislature, rejected the provisions of the Sheppard-Towner Act. Thus, five States have made definite rejection of Federal aid offered through that Act. Most of the State Legislatures will meet in January, 1923, and final action will be taken by those bodies on this matter in the States where the Legislatures have not already accepted or rejected the provisions of the Federal maternity and infancy law, through which the national Government offers financial aid to States which will carry out a program approved by a Government board."—A. M. A. Bulletin.

INTRATRACHEAL INSUFFLATION ANAESTHESIA*

By MARY KAVANAGH, M. D., San Francisco
Instructor of Anesthesia, University of California Hospital, San Francisco

One of the greatest dangers of intrathoracic operations is the occurrence of pneumothorax as soon as the pleural cavity is opened. This, when limited to one side, while not fatal, always causes more or less serious respiratory embarrassment. When both cavities are opened the result is generally fatal. As it not infrequently occurs in operations upon one side of the thorax that the opposite lung is more or less incapacitated as a result of injury or disease, the desirability of avoiding the serious consequences of pneumothorax has long been appreciated.

The word *pneumothorax* was coined in 1803 by Itard, a French physician. The condition it describes barred for practically one hundred years the chest cavity to the knife. Modern thoracic surgery dates from 1896, when Quénu first made known the idea of restoring in pneumothorax artificially by differential air pressure the disturbed equilibrium of the lung, and Tuffier advocated the use of insufflation for the performance without pneumothorax of operations requiring the incision of the pleura. Quénu's apparatus was constructed on the lines of a diver's helmet in which the head of the patient was placed with a sponge saturated in chloroform. The air in the helmet was compressed and the pleural cavity opened. Tuffier introduced a narrow, slightly curved copper tube into the larynx and trachea. Matas of New Orleans was the first in the United States to become interested in thoracic surgery. He introduced the *Feel-O-Dwyer* type of apparatus for artificial respiration. The anaesthetic was given by means of a funnel attached to a T-tube. The main tube was introduced into the larynx and trachea. In 1898 Parham of New Orleans used the Matas apparatus in performing a resection for tumor of the bony wall of the chest—the first thoracic operation of record in this country. In 1903 the Sauerbruch cabinet was invented; and 1904 marks the real beginning of thoracic surgery by the transpleural route. For its performance Sauerbruch had built a chamber of about five hundred cubic feet contents, constructed of iron and glass, inside of which the operation is performed. Over the opened pleural cavity the air pressure is reduced below atmospheric pressure, while the patient, whose head is passed through an opening in the wall, breathes in atmospheric pressure. In quick succession, chambers were built in Berlin, Cologne, Vienna, St. Petersburg, and other places in Europe. Size of the chambers averages about six hundred cubic feet contents; the largest one at Vienna contains about 750 cubic feet. Their height is usually seven feet six inches.

The reverse proposition was also taken up by Sauerbruch, and after him Peterson, and Engelken constructed positive differential pressure cabinets, Peterson of wood and Engelken of iron and glass;

* Presented to the Pacific Coast Association of Anesthetists, May 16, 1922.

boxes of about fifty cubic feet contents, into which the head of the patient is passed through an opening in the side wall. The inside air pressure is then raised above atmospheric pressure. The patient breathes compressed air, while outside of the cabinet the pleural cavity is opened in atmospheric pressure. The anaesthetic in operations with these chambers and cabinets is applied in the ordinary way—with ordinary face mask and ether by the drop method. The anaesthetist frequently became partially anaesthetized. The construction of these chambers and cabinets was such that the surgeon could not see the head of the patient, and the anaesthetist could not follow the operation. Telephones were then installed, but the open air-pipes connecting the pump cylinder with the chamber or the cabinet made of the latter practically a part of the pump cylinder, in which the clicking of the valves, the hissing noise of the air in the air-pipes, and the boiling of the air through the water valve combined to make such a noise that the telephone was inaudible. Ventilation was deficient, the air being renewed only once in ten or fifteen minutes. The anaesthetist's attention was taken from the patient to regulate the pressure and other duties, which should have been done by others.

These inconveniences were avoided in the positive differential pressure apparatus of Bauer. The head of the patient is enclosed in an air-tight box about five cubic feet contents, in which the air is changed from four to five times every minute. The anaesthetic is applied by mask in the ordinary way. Openings are provided in the side of the box, through which the hands and arms of the anaesthetist are introduced, and then made air-tight by means of rubber gloves fastened inside of the box. It is thus from the outside that the anaesthetist applies the anaesthetic and manipulates the head of the patient, which he sees before him below a pane of glass. In 1907 Green and Janeway had constructed a positive pressure apparatus of the Bauer type, but modified and improved as to the valve action and mechanical appliances for artificial respiration during anaesthesia. In 1908 Willy Meyer's Positive Pressure Cabinet appeared. A cabinet of about eighty cubic feet contents, large enough for two anaesthetists, was built of wire screens and made air-tight from the inside by means of a bag of rubber sheeting, through which conversation between surgeon and anaesthetist can be carried on. The anaesthetists within are placed in a current of fresh air; the exhaust is near the head of the patient, so that the vapors of the narcotic are absorbed by the patient only. The air is changed once every minute. Outside, against one side of the cabinet and projecting far out from the same, a pyramidal box was placed opening inward and closed in front by a rubber collar through which the head of the patient is passed. The bottom of this head-box is horizontal, and serves to carry an adjustable support for the patient's head, offering besides room for instruments, etc. The top of the box pitches downward and consists of a large pane of glass, below which the patient's head can be seen from the outside. Above the pane is placed a mirror in which the anaesthetists, glancing up, see the field of operation reflected. The cabinet has an air-lock by means of which the anaesthetists can be reached without interruption of the difference in pressure. There is room inside for oxygen-tanks and for apparatus for applying the anaesthetic. The anaesthetists have access to the head of the patient, with plenty of room all around the same for carrying on whatever manipulations are required during anaesthesia. Lately, the inside covering of rubber sheeting has been replaced by copper sheeting, and the use of rubber sheeting been restricted to sound-windows for conversation between surgeon and anaesthetist in the two vertical sides of the head-box. Another sound-window is arranged in the copper near the pressure valve for conversation between anaesthetist and the mechanic. Later, the opening in the wall for passing the patient's head into the open air was omitted. Instead, the patient's head is placed in a positive differential pressure cabinet erected within the negative chamber. The size of the latter has been increased to approximately one thousand cubic feet contents (16 x 8 x 8). When the patient's head is in the positive cabinet, his body rests in the negative chamber on the operating-table in front of the positive cabinet. The air supply is so apportioned that the pressure within the cabinet, as well as within the chamber, responds immediately to the slightest change in the setting of the valves. By opening or closing these valves differences in pressure are produced, the extent of which is read on the gauge. Using the gauge as guide, the valve can, therefore, be handled in such a way that the pressure rises and falls between limits determined by the surgeon.

Reduction in the size of cabinets from six hundred to fifty cubic feet contents, and from fifty to five cubic feet proved that cabinets could be dispensed with. Its place has been taken by the mask and intubation tubes and an apparatus forcing ether vapor through the same. Of the mask type are the apparatus of Brat-Schmieden and of Tiegel. In both the drop method is used, in combination with an oxygen tank, the oxygen stream carrying the anaesthetic to the lung. The pressure in the lung is maintained by expiring against either a spring valve (Schmieden) or a water column (Tiegel). The intubation type is the apparatus of Kuhn. A tube is introduced into the trachea and compressed air is mixed with ether vapor blown through the same into the lung.

In 1908 experiments to overcome the deleterious effects of pneumothorax in operations upon the thoracic viscera were started. The experiments mainly followed two plans:

First. To increase the air pressure within the bronchial tubes and thus prevent a collapse of the lung when the negative pressure on the surface of the lung is removed by opening and admitting air to the pleura.

Second. To diminish the atmospheric pressure on the exterior of the lung when the chest is

opened, while maintaining the normal pressure of the air entering the trachea.

Experiments with the first method have generally been carried out by means of a snugly fitting tracheal cannula or intubation tube and some form of an air-pump or bellows.

Experiments by the second method—by placing the animal's body below the neck in an hermetically sealed chamber from which a certain amount of air has been drawn. This was the Sauerbruch cabinet, the then most satisfactory negative pressure apparatus. When sufficient air is withdrawn to render the negative pressure equal to 10 or 12 cm. of mercury it was found that in opening both pleural cavities the lungs did not collapse, but respiration continued without the slightest embarrassment.

F. T. Murphy of Boston has devised an airtight helmet which incloses the patient's head and neck, and in which the air pressure is increased and maintained by water displacement. Since that time experimental work has been towards employment of methods of positive intratracheal pressure rather than those utilizing negative pressure as in the Sauerbruch cabinet. Then came the Tiegel positive pressure apparatus and next came a portable positive pressure cabinet of Janeway and Green. Many others worked along these lines, but it remained for Auer and Meltzer to perfect and popularize the intratracheal anaesthesia. This is the method of introducing in the trachea a flexible tube, the diameter of which is much smaller than the lumen of the trachea, and they established the facts that pulmonary ventilation might be maintained by a constant stream of air or oxygen, under definite pressure being blown in the trachea and which returns along the space between the tube and the wall of the trachea and escapes through the mouth and nose. This insured the proper oxygenation of the blood, inflation of the lungs, favored the continuance of cardiovascular circulation, and permitted the induction of narcosis by means of a volatile anaesthetic. The result is an ideal anaesthesia because the dosage can be accurately adjusted, and by this means adequate and efficient respiration can be carried on, when, for any reason, the normal respiratory mechanism is embarrassed or fails completely. The embarrassment caused by spasm of the glottis, accumulation of mucus in the pharynx, and the dropping backward of the tongue are entirely avoided, and the demonstrated impossibility of foreign substance present in the mouth or pharynx entering the trachea or bronchi.

The Auer-Meltzer is a comparatively simple apparatus, and it abolishes the cumbersome uncertain appliances of the past and opens the thorax to the progress of surgery. The work of Auer and Meltzer, Elsberg, Flint and others has proved that intratracheal anaesthesia is not only a successful solution of an important phase of intrathoracic surgery, but is a safe adventure.

In 1912 Saxton Pope of San Francisco constructed an apparatus involving the Auer and Meltzer theory. Its principal features are compactness, a means of the accurate regulation of the proportion of ether and air given, electric heating to volatilize the ether and a pressure and safety valve attachments. This apparatus has been used for intratracheal anaesthesia with the most satisfying results.

To develop the technique of this form of anaesthesia I gave a series of intratracheal anaesthetics in 1913 to forty-two cases in general surgery. Since then I have had for intracheal anaesthesia the following cases: Mediastinal tumor, 4; carcinoma of mouth, 1; carcinoma of larynx, 3; carcinoma of tongue, 3; carcinoma of esophagus, 4; sarcoma of jaw, 1; carcinoma of cheek, 1; carcinoma of lip, 2; tracheoplasty, 2; diaphragmatic hernia, 1.

The technique for intratracheal anaesthesia is as follows: The patient is thoroughly anaesthetized by the gas and ether sequence. Buccal or nasal anaesthesia is continued to maintain anaesthesia during the stage of introducing the laryngeal catheter. The side-mouth gag is inserted. The first and second finger of the right hand are put well down the throat, the epiglottis located and pushed well forward; then the introducer loaded with the disconnected catheter (a No. 21 or No. 22 French catheter) is passed along the finger into the rima glottidis. As soon as the catheter is in the trachea you realize the fact by the hissing of the air in the tube on respiration of the patient, or by coughing of the patient, who is lightly anaesthetized. This is not an easy procedure, as the catheter may be inserted in the esophagus more readily than into the trachea. When the tube is in place it is then pushed down a distance of 25 or 30 centimeters from the teeth, and the introducer slipped off. Then the connection is made with the machine for intratracheal anaesthesia. A far better method of introducing the catheter is by means of the laryngoscope.

Some of the patients complained of sore throat after recovery from the anaesthesia, some had laryngitis, but this was due more to the unsuccessful attempts at intubation than the irritation of the tube in place. No case developed pneumonia. The tracheal tube is left in until breathing is good and coughing warns us of the return of the laryngeal reflex. At the end of an operation the patient can be roused within two to five minutes by giving straight air.

Continuing the history of intratracheal anaesthesia, we find the group of cases in which intratracheal anaesthesia has been found to be so highly advantageous is very limited, and that the Meltzer method has been supplanted by the pharyngeal method of Connell. Pharyngeal insufflation has supplanted intratracheal in all operations, even those requiring positive pressure for intratracheal work—except in such cases where collapse of the trachea is threatened—and eliminates the most serious complication of intratracheal anaesthesia, oedema of the epiglottis.

The apparatus illustrated is a modification of Pope's original apparatus, and following the suggestions of Dr. Sheldon, a member of the house staff, I now possess a practically noiseless motor which he devised.

(University of California Hospital).

BOWEL OBSTRUCTION FOLLOWING OPERATIONS OCCURRING DURING CONVALESCING PERIOD *

By ALANSON WEEKS, M. D., and
LEROY BROOKS, M. D.
(From the Department of Surgery, University of California Medical School, St. Luke's Hospital).

The menace of bowel obstruction following an abdominal operation is constantly with us. We have had personal experience with bowel obstruction following the simplest types of work in the peritoneal cavity.

The cause of death in these patients is a most interesting phase of the subject. The amazingly painstaking experimental work of men in the laboratory such as Whipple, Bacon, Anslow and Eppler, of Hartwell and Hoguet, and of Alvarez and Ellis has aided the surgeon in reducing the mortality. Still far too many of these cases end fatally and it is relatively unimportant to the practical surgeon whether the toxemia is due to a toxin from the intestinal mucosa or from intestinal contents, or whether it is due to shock or to dehydration, unless it points a way to relief. Surgeons have known since Kocher's early work that the intestinal contents in patients suffering from obstruction are toxic and all of them have practiced repeated gastric lavage.

The work of the men mentioned above has taught the clinical men that the toxic contents of the obstructed bowel tends to accumulate in the upper intestine and enterostomies are now done in this portion of the gut. However, the mortality rate is appalling and will continue to remain high until means are developed which will aid in making an early, certain diagnosis. Whipple and his co-workers lay stress upon the increase of the nonprotein nitrogen of the blood as a prognostic sign, while Bacon, Anslow and Eppler claim to have shown that this increase is due entirely to dehydration.

We recognize functional and mechanical obstruction following operation, and the life of the patient depends upon the rapidity with which we are able to diagnose the mechanical type. We must admit a functional foundation for intestinal paralysis. For instance, the organism in self-protection in the event of peritonitis puts the bowel at rest; also we meet paralytic ileus in other overwhelming toxemias where the peritoneum is not involved. Whether this is due to stimulation of the sympathetic nervous system or disturbance in the normal intestinal gradients is still an open question. Probably both have an influence.

We have seen an ileus in a patient with a large crushing injury to the thigh with profound toxemia, and autopsy showed the peritoneum, the intestine, and the mesentery free from inflammation. Similar findings are not at all uncommon in pneumonias.

We are reminded of one patient in whom we resected the cecum and part of the ascending colon with an end to end anastomosis for cancer, who developed an ileus as nearly as could be observed shortly after the operation. The patient was not in shock upon leaving the operating room. She failed to be relieved by liberal administration of fluids both subcutaneously and intravenously, repeated gastric lavage, and even opening of a presenting loop of intestine with irrigation did not prevent a fatality. This had to be recognized as functional paralysis because at autopsy the field of operation was entirely walled off from the general cavity, there was no general peritonitis, and the anastomosis was patent, but the whole small bowel was enormously dilated.

Another patient with a bullet wound of the abdomen rode forty miles in an automobile and was operated upon ten hours after the accident. A loop of the jejunum was perforated four times and the descending colon twice. The peritoneal cavity contained a considerable amount of intestinal content and the peritoneum had thrown out a plastic exudate. Twelve inches of the jejunum was resected, side to side anastomosis done and the holes in the colon sutured. The patient did well until the third day when there was a profuse discharge of pus and the abdomen was so extremely distended that the pit of the stomach rose domelike from the chest. A diagnosis of functional obstruction was made and a duodenal tube put in the stomach and strapped to the patient's chin with connecting tube which hung into a pail partly filled with water and placed beside the bed. The tube was left twenty-four hours and the patient slept while his stomach was washed at intervals. He was furnished with plenty of fluids subcutaneously and enormous quantities of black material drained into the pail. After this he had a smooth convalescence.

The great danger to our patients is that the surgeon often fails to make a diagnosis of mechanical obstruction because he must recognize this functional cause, or he lacks the moral courage to submit his patient to the ordeal of a second operation soon enough.

The mechanical causes of bowel obstruction during the period of convalescence are very numerous. One patient from whom a chronic appendix had been removed, when we first saw her had fecal vomiting. The abdomen was promptly opened and the coils of the intestine were found glued to the field of operation in such a way that a kink was formed and obstructed the lumen. As the loops were freed peristalsis was rapidly established even before the abdomen was closed. This patient promptly recovered.

A young girl who had an acute, gangrenous appendix removed developed obstruction within a week following appendectomy. Upon reopening the abdomen it was found filled with a thick jellylike material which had caused a gluing together of the coils. The patient was reopened four times for obstruction following the initial operation and the cause was no doubt the rapidity with which the peritoneum threw out the fibrinous exudate. She recovered and for a number of years has had good health.

Another patient upon whom gastroenterostomy and appendectomy were performed for stomach ulcer, developed a pelvic peritonitis and partial obstruction which cleared up to be followed in the course of a week by complete obstruction. Upon

* Read before the Fifty-first Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May, 1922.

reopening the abdomen the pelvis was found matted with coils of small intestine around a rather large abscess. The abscess was drained with large tubes. The futility of any effort to unwind the obstruction in the bowel was evident, and a catheter was placed in a distended loop of the upper jejunum which drained freely for three or four days. The patient made an uneventful recovery. He had stools in four days and the opening in the small bowel closed very soon. We have been unable to account for the pelvic abscess.

Another patient from whom a gangrenous appendix had been removed made an uninterrupted recovery and was about to leave the hospital on the fourteenth day when he suddenly, as is usual in the mechanical obstruction, complained of violent pains in his abdomen. Reopening of the abdomen revealed a volvulous of the small bowel enormously distended, impacted in the pelvis. The site of the twist was near the former site of the appendix and adhesions had probably helped to cause the obstruction. There was no peritonitis. This patient promptly developed paralytic ileus which caused his death.

A nurse who was about ready to resume her duties following the removal of an acute, unperforated appendix, developed a bowel obstruction. Immediate reoperation revealed a volvulous near the site of the former operation which was easily freed and the patient recovered.

A patient upon whom a gastroenterostomy was performed a month before gave a history of very frequent vomiting following the operation. It was found at the secondary operation that the stomach had dragged the jejunum through the opening in the mesocolon which had caused almost complete obstruction of the bowel above and below the new opening. The mesocolon was freed about the gastroenterostomy opening, which was ample in size, and the stomach pulled through for three-fourths of an inch and the mesocolon stitched at this site. This patient recovered.

This is a sufficient number of examples of bowel obstruction during the convalescing period following laporotomies to cover the field. Others have reported obstruction following the Gilliam operation through a loop of small bowel caught about the round ligament in its new position, which has led most surgeons who use this operation to close the opening. Others have reported post-operative obstruction due to thrombosis of the mesentery veins, and ligation of the blood supply of the transverse colon in doing resection of the stomach has been reported. A loop of gut may be caught in the abdominal incision by a separation of the deep layers of the wound and for this reason the incision should be examined in every convalescing patient registering symptoms of intestinal obstruction. A loop of gut also may be caught in the loop of bowel following a posterior gastroenterostomy.

The differentiation between functional and mechanical obstruction is often difficult to make. A correct history and close observation is called for in each case. Early differentiation is imperative because the treatment of the types is radically different.

Functional paralysis usually comes on shortly after operation or after the development of peritonitis or toxemia. The patient does not have the grinding-like pains through the abdomen and is usually apathetic. The abdomen is tremendously distended and symmetrical; vomiting occurs, if at all, several hours after the onset of the distension and it is apt to be of the spitting-up type; gas enemas and irrigations fail to relieve the distension, but with persistence enough gas can be removed to furnish some relief and valuable information. If not relieved these patients develop rapid respiration and rapid heart action and die from toxemia, hypostatic pneumonia and failing blood pressure.

Mechanical obstruction rarely occurs before the third or fourth day and usually not until several days after operation. The patient may or may not have peritonitis. The first symptom to appear is grinding-like pains in the abdomen occurring at intervals, which is followed by vomiting usually violent and often projectile, and the patient shows decided anxiety. The distension of the abdomen and the time of the onset of vomiting depends much upon whether the obstruction is high or low in the bowel. The character of the pain is the pathognomonic symptom and is always present if an accurate history is obtained. Enemas and irrigations fail to produce results except at first the return may contain some particles of fecal matter, but there is no gas, except that which may be injected from the enema tube. Leucocytosis, probably due to dehydration, is present. Running pulse followed rapidly by shock, and death soon follows unless relief is furnished.

In the prevention of intestinal obstruction gentle handling of the tissues during operation is the most important prophylactic measure, and for this reason we advocate wide abdominal incisions.

The treatment of functional ileus is repeated gastric lavage; or better, a duodenal tube with connecting tube which hangs over the side of the bed in a pail partly filled with water; repeated enemas and high irrigations with lubricating liquids. Stimulation of the bowel with Pituritin or Eserin in sufficient doses, each time following immediately with irrigations of the bowel which should be continued from forty to sixty minutes.

The treatment of mechanical obstruction is by operation immediately after the earliest possible diagnosis. In these operations speed is to be desired. If the obstruction is difficult to relieve it is better to put a catheter in the upper small bowel and close the abdomen. Irrigations through this catheter will drain off the toxin and the patient should be treated for shock. There will be time enough to do further operative work if necessary when the patient's condition is less critical.

In both types of obstruction there is secreted into the lumen of the intestine large quantities of water and toxins so it is evident that these patients must have a sufficient quantity of fluids. We give routinely normal salt solution subcutaneously and glucose solutions intravenously as often as required, which furnish the patient with nourishment as well as with fluids.

ABSENCE OF THE PROSTATE ASSOCIATED WITH ENDOCRINE DISEASE *

By H. LISSER, M. D., San Francisco

Whether the prostate deserves to be classified among the incretory glands is as yet extremely problematical. However, certain investigations concerning its possible harmonic activity have been undertaken. For example, DuBois and Boulet in 1919 demonstrated that intravenous injections of extracts of normal prostate cause a contraction of the bladder, whereas, hypertrophied human prostate had no such effect. These findings led the authors to conclude that there is an internal secretion of the prostate which acts as an excitant of the vesicle muscles.

Bogoslovsky and Korentchevsky made observations on the metabolism of two normal and six castrated dogs which were given intravenous injections of emulsion of prostate or of testicle or both. They conclude that the prostate constitutes a powerful stimulant to the internal secretion of the testicle, and the internal secretion of the testicle exercises a stimulating influence on exchange of protein substances especially.

Macht and Matsumoto in 1920 performed experiments to determine whether prostatic extracts in vitro had any specific action on isolated genitourinary organs. They concluded that no specific action existed. Macht recorded further endocrinological studies of the prostate in 1921 and reported that the feeding of prostate hastens metamorphosis of the frog and salamander larvae, but that unlike thyroid it causes no shrinkage of the animals.

Castration was one of the earliest of surgical procedures and in 1775 John Hunter called attention to the fact that castration carried out in *youth* or infancy causes *hypoplasia* or want of development of the prostate. About a century later Griffiths, White and Guyon added the interesting fact that castration in *adult* life causes *atrophy* of the prostate.

In 1893 Griffiths enlarged our knowledge in respect to gonad insufficiency, at the same time introducing the term "eunuchoid" to describe a type of individual who was *lacking* in testicular secretion but had not been castrated. He reported two cases of men aged 30 and 21, respectively, who were of peculiar form, narrow shoulders, broad pelvis, round and plump neck, beardless faces, high-pitched voices, large breasts, and whose genitalia were infantile. In one patient practically no prostate was palpable per rectum; that is to say, a thickening was felt, but no definite gland. The other was examined post mortem and the prostate was hardly more than one-third of its natural size. Microscopic glandular tubules could be detected in the prostate, but they were comparatively few.

Clinical hyperpituitarism produces gigantism before adolescence and acromegaly after puberty. In earlier stages of acromegaly we are acquainted with examples of excessive sexual libido, and in gigantism with instances of premature acquisition of sex power and secondary sex characters. Most of these patients, however, come to the physician in the late stages of the disease when pituitary *inactivity* has supervened, and then we find, in the female, characteristic obesity and amenorrhoea and sterility and in the male diminished libido and potentia, and in both a high degree of atrophy of the sex glands. *This well recognized relationship between the pituitary and the sex apparatus is exemplified even more emphatically in primary hypopituitarism.* The Froelich syndrome discovered in 1901 consists of skeletal undergrowth, obesity, and sex infantilism; the Lorain type likewise demonstrates skeletal undergrowth and sexual aplasia, but *without* adiposity; the Neurath-Cushing variety of dyspituitarism consists of skeletal *overgrowth* with adiposity and sexual infantilism; *the common demoninator in these clinical disturbances is sexual infantilism.* Whether these syndromes are actually due to pituitary insufficiency is at present disputed. Bailey and Bremer and others have reproduced diabetes insipidus, and even obesity with sexual infantilism, in dogs by puncturing the hypothalamus, using the lateral approach of Paulesco and Cushing, giving perfect exposure of the pituitary gland. They have accomplished these results with startling uniformity and careful serial sections of the pituitary gland have shown it to be absolutely free from injury. However, until further investigations settle this important question it will be best to continue to refer to the syndromes of Froelich and Lorain as examples of clinical hypopituitarism.

Attempts have been made to produce hyperpituitarism experimentally. Those that chose transplantation of pituitary substance as a method of producing hyperpituitarism failed in their efforts. Goetsch fed anterior lobe pituitary, posterior lobe pituitary and whole gland pituitary to young rats and obtained very positive results which, however, have not been confirmed. The feeding of pituitary anterior lobe extract caused more vigorous body growth than in the control animals and stimulated earlier and more active genital development. In his report he specifically mentions the *effect of anterior lobe feeding on the prostate gland which showed, like the sex glands, an earlier development and activity.*

Many investigators (notably Crowe, Cushing and Homans, Blair-Bell, and Aschner) proved by producing hypopituitarism experimentally that the genital apparatus is markedly retarded in its development and that this hypoplasia included the prostate as well as the testes, penis and vas deferens. Whether their results were really due to pituitary insufficiency or resulted from accidental injury of the neighboring brain tissue remains to be settled.

In view of the striking genital abnormalities repeatedly emphasized in clinical hypopituitarism, and in view of the specific mention of undeveloped prostates in experimental hypopituitarism, it seemed rather surprising that no reference to the prostate had been made in the innumerable case reports of Froelich, Lorain and Neurath-Cushing hypopituitarism. Accordingly, in 1920, I placed on

* Read before the section on Pediatrics at the fifty-first annual meeting of the Medical Society of the State of California, Yosemite, 1922.

record (The New York Medical Journal, March 2, 1920) five cases of pre-adolescent hypopituitarism, in three of whom no prostate could be felt by rectal examination, and in two of whom only a very tiny diminutive organ could be recognized.

Since that publication several more cases have been discovered so that to date there may be reported *fifteen cases of hypopituitarism* (eight of the Lorain type, five of the Froelich syndrome and two of the Neurath-Cushing type) *and three cases of primary gonad deficiency*. Of the eighteen cases *no prostate could be felt in thirteen cases and only a tiny diminutive organ in the remaining five.*

The prostate is large enough normally in childhood to be easily felt and pediatricians especially are urged to make rectal examination in boys who show other stigmata of infantilism.

Not much is to be gained at this time by elaborating theories concerning absent or diminutive prostate in hypopituitarism. It is established that atrophy occurs after castration; we also know that testicular aplasia occurs in hypopituitarism. *Whether the prostatic aplasia or atrophy in hypopituitarism is due directly to the lack of pituitary secretion or whether it follows upon testicular insufficiency is difficult to decide. As it happens, all the cases that show absent or diminutive prostates likewise show tiny and insufficient testes.*

The above data summarizes briefly a paper to be published shortly which will discuss the question more fully and which will include detailed histories of the eighteen cases together with their photographs.

"The Great Question"—We hospital administrators live in the midst of a mass of questions. They rise and confront us on every hand. They grow up like thistles in the field—questions social, economic, financial, nursing, medical, industrial and international. We walk in a forest of them, some tall as trees and seemingly as big in girth, while others form a jungle of little irritating problems that catch at us and tear us as we try to make our way. Everybody seems so busy asking questions that nobody seems to have time to answer them. One favorite way of trying to answer them is to send out a questionnaire; as if we had moved forward toward the answer to one question by raising forty more. Never mind whether anyone answers or not; send out the question, then feel that we have done something. The sign of the times seems to be a huge question mark.—From the Presidential Address of George D. O'Hanlon, read before the Twenty-fourth Annual Convention of the American Hospital Association, published in The Modern Hospital.

Drifting or Rowing—You are either drifting downstream with the tide and the dead ones, or you are pulling for all you are worth against the current of events. You cannot anchor, for life is one continuous voyage. You are either reading, studying, working, or you are fooling away your most valuable asset—time. If you are trying to improve yourself you are going ahead. If your brain is full of nonsense, you can bet your boots you are drifting down the stream.—The Silent Partner.

SOME OUTSTANDING FEATURES OF RECENT PROGRESS IN SURGERY*

By GEORGE THOMASON, M. D., F. A. C. S.,
Los Angeles

It is, of course, quite impossible within the limits of our allotted time to even touch upon all the phases of recent advances in surgical practice. We must content ourselves with briefly citing the outstanding features of our subject.

Biliary Surgery—One of the most important advances in biliary surgery has been in connection with the pre-operative and post-operative care of jaundiced patients. As it is well known one of the chief risks of operating in the presence of jaundice is the post-operative bleeding, not by reason of the slipping of a ligature from a vessel, but from the multiple points on abraded surfaces, due to diminished coagulability of the blood. Most of the fatalities due to intro-abdominal hemorrhage in jaundiced patients are in cases where the coagulating time of the blood is nine minutes or more. It has been found that calcium chloride in 10 per cent solution, 5 cc., injected intravenously during a three or four-day period will greatly reduce the coagulating time of the blood.

In addition these jaundiced patients should be fed large quantities of carbo-hydrates and given 15 per cent glucose in tap water by proctoclysis and 3000 or 4000 cc. of water by mouth every twenty-four hours, to hydrate the patient and to promote elimination of the toxic bile pigments.

Opie, as the result of his experimental work, believes that carbo-hydrates prevent disintegration of body proteins when the individual is in a state of toxemia. It is believed that the calcium is beneficial, not only in lowering the coagulating time of the blood, but in decreasing toxemia by uniting with the circulating bile pigment. In addition to this Crile recommends an extremely light form of nitrous oxide anesthesia, the avoidance of any narcotic, especially morphin. Hot packs to the liver continued intermittently after the operation until convalescence is established, one or more transfusions of blood during the first week, and in gravest cases, if possible, dividing the operation into two stages, are further protective features for the jaundiced patient. Recently a personal case, a man extremely ill and heavily jaundiced, was treated by the calcium method and the blood coagulating time was reduced from more than nine minutes to seven minutes within two or three days, and largely under local anesthesia a cholecystgastrostomy was successfully performed.

In the development of biliary surgery there is an outstanding feature now quite generally accepted by common consent, namely, that it is extremely unwise and injudicious to perform in one stage an operation involving interference with the pelvic organs and the gall-bladder. Experience has been a very effective teacher in this respect. It is not a question of speed or dexterity on the part of the surgeon, for the fatalities occur in this class of cases, for instance, hysterectomy and cholecystectomy combined, where

* Read before the General Session of the Medical Society of California at Yosemite National Park, May 17, 1922.

the lapse of time has been remarkably short. Practically all surgeons of any considerable experience now do a two-stage operation where gall-bladder involvement is determined in connection with pelvic pathology. The striking statement of the late John B. Murphy, although referring to a different surgical procedure, is most applicable to the man who persists in going the limit in a one-stage operation: "It is complimentary to his daring, but derogatory of his judgment and hazardous to his patient in the extreme."

Interesting and helpful features are developing as to the possible and probable causes of gall-stones. Rosenow's studies have persuaded him that gall-stones result from cholecystitis, being caused by bacterial invasion of the gall-bladder wall. Henes thinks hypercholesterenemia the primary and fundamental etiological factor in the production of gall-stones. Certain it is that many gall-bladders with cholesterin stones give no evidence of infection. Aoyama, producing gall-stones by subcutaneous and oral feeding of cholesterin, has given support to Henes' contention. Rothschild and Felsen noted very high cholesterenemia in obstructive jaundice *due to stone*, while in jaundice due to hepatic lesion the cholesterin content was normal or subnormal. Certainly these observations strongly suggest that the routine examination of the percentage of cholesterin in the blood might be a valuable diagnostic feature in biliary conditions. Next to the appendix, the gall-bladder furnishes the most frequent intra-abdominal lesion requiring surgical interference, consequently progress in the direction of earlier and more accurate recognition of gall-bladder involvement has been most marked. During all the developmental period of biliary surgery there has been considerable swinging of the pendulum of opinion as between cholecystostomy and cholecystectomy; also as to whether the dissection should begin at the fundus or at the ducts; again as to whether or not the duct and artery should be ligated separately, and as to whether or not drainage should be routinely used following cholecystectomy.

There is great diversity of opinion as to the function of the gall-bladder, but probably it is principally a concentrator of the bile. Thus far the removal of the gall-bladder has apparently not been followed by any particularly demonstrable deleterious effect upon the body beyond a dilatation of the extra-hepatic ducts. Sufficient time has now elapsed to permit of the conclusion that the end results of cholecystectomy are sufficiently better than cholecystostomy to justify the more radical operation except in special cases where distinctly contra-indicated.

The opinion seems to be gaining ground that more frequently than formerly supposed there is variation in the relation and termination of the hepatic and cystic ducts and that isolation of the ducts and more accurate determination of their relationship may be obtained in dissecting the gall-bladder from the fundus toward the ducts. Isolation of the cystic duct and its separate ligation is a factor of safety against injury of either the hepatic or the common duct. But aside from this there seems to be no particular advantage in the separate ligation of the duct and artery. Judd expressed to me his personal opinion that it did not make the slightest difference.

Undoubtedly the tendency is strongly toward closing without drainage following cholecystectomy; but this practice involves the necessity for very thorough hemostasis, careful peritonization to prevent leakage of bile from the abraded liver surface, and thorough securing of the stump of the cystic duct by the ligature to prevent its re-opening. There are still many good men, however, who are earnestly pleading that drainage be provided for a few days following cholecystectomy.

There has been great advance in the matter of plastic and repairative work on the bile ducts in the use of pedicled flaps of bowel or stomach or, better still, by the reimplantation of the duct either into the stomach or duodenum.

Gastric Surgery—Since 1881, when Billroth did the first successful pylorectomy and Wolfler the first gastro-enterostomy, gastric surgery has passed through the era of almost utter abandonment, due to disappointing results and excessive mortality, to that of perfected mechanical facilities, highly developed technique and diagnostic acumen, bringing gastric surgery to the point of brilliant achievements equal to that of any phase of surgical endeavor. The period of disappointing results from ill-advised gastro-enterostomies led to a more careful differentiation of cases and to more specific classification of indications for this procedure until it now rests upon a much less questionable basis than in the days of its much more frequent abuse. Moynihan believes that 90 per cent of the unfavorable results of gastro-enterostomies can be accounted for on the basis of the operation being done without organic lesion, that is, for functional disorders or for chronic diseases elsewhere than in the stomach.

Most of the discussion in gastric surgery now chiefly involves the question of the proper surgical treatment of gastric and duodenal ulcer, whether ordinary gastro-enterostomy is sufficient for single pyloric and duodenal ulcers or whether circular excision of the ulcer with gastro-enterostomy should be adopted. Deaver believes if the ulcer is allowed to remain it may or may not heal, and his experience has led him to resect the ulcer in addition to doing a gastro-enterostomy, thus reducing the chance of carcinoma and of subsequent hemorrhage or perforation. In Bull's clinic in Christiania, simple gastro-enterostomy has seemed to give as good results as resection in ulcers *near* the pylorus and in the duodenum, but far less satisfactory results are obtained from gastro-enterostomy when the ulcers are at a distance from the pylorus. Judd believes that for ulcer in the cardiac end of the stomach it is better to do a gastro-enterostomy in addition to excision because at least one-third of these patients have recurrence of symptoms where mere excision without gastro-enterostomy is done. He believes the rhythm is broken when certain portions of muscle are removed, causing two waves to come together so that the stomach does not properly empty. When gastro-enterostomy is done and the ulcer not excised, 65 per cent recover and in 35 per cent symptoms will recur. Judd believes

gastro-enterostomy without excision is the procedure of choice for duodenal ulcer. Curt Methling of Leipsic observes that for ulcer of the stomach or duodenum near the pylorus simple gastro-enterostomy gives a very satisfactory immediate result, but that after a few months there is a sense of pressure, more or less hypo-chlorhydria, anacidity and chronic gastritis, just as unpleasant in its phenomena as the original ulcer. The bile flowing through the anastomotic opening, combining with the acid, controls the hyper-chlorhydria for the time, but later the effect of the bile in the stomach is to injure the secretory activity of the gastric glands and to eventually produce a chronic anacidity with gastritis.

It seems probable that an entero anastomosis, short circuiting the proximal and distal jejunum three to four inches from the gastro-enterostomy will overcome this interference of the admixture of bile with the stomach contents. This entero anastomosis can be very quickly and easily done with a small Murphy button, the two halves of the button being dropped into the proximal and distal jejunum when the bowel is opened for the gastro-enterostomy.

With the relative frequency of carcinoma being superficial upon an old ulcer one can not escape the conviction that wherever possible all gastric ulcers should be excised. It is equally true regarding the danger of subsequent perforation. Nathan Winslow recently reported twenty-nine cases of perforated gastric and duodenal ulcer which were operated. Fourteen recovered and fifteen died. Twenty-three of the twenty-nine cases gave histories of gastric disturbance typical of ulcer, for which had proper treatment been instituted the emergency operation with high mortality might have been avoided. Progress in the surgical treatment of gastric carcinoma has been very gratifying. Results showing at least 25 to 30 per cent of three to five-year cures. It is now believed that in fifty per cent of gastric carcinomas there is no metastasis, consequently a much larger percentage of these cases lend themselves to favorable surgical interference than was formerly supposed.

Experience has seemed to demonstrate that the Billroth II and the Mayo modification of the anterior and posterior Polya operations give the best results in partial resections of the stomach. With the regular posterior Polya I believe there is much greater danger of back pressure causing a reopening of the blind duodenal stump, possibly through too complete incorporation of the jejunum with the heavier gastric walls, producing more or less obstruction. I have twice had the experience of duodenal leakage after performing the posterior Polya. Where sufficient stomach is left so that it can be brought through the opening in the transverse meso-colon it seems the modified Polya is the best type of gastric resection; but where it is necessary to remove more than one-third or one-half of the stomach the modified anterior Polya is decidedly the best. The emptying of the stomach along the lesser curvature into the distal jejunum, through a small opening, the overlapping of the sutured stomach by the jejunal walls and the saving of time made possible by this technique makes of this operation an exceedingly gratifying gastric operative procedure.

Babcock joins the duodenum to the lesser curvature of the resected stomach and overlaps the sutured portion of the stomach with the duodenal walls and thus avoids the "Fatal Angle" and re-establishes a normal relationship between the stomach and duodenum.

Thoracic Surgery—From among the remarkable developments in thoracic surgery during recent years we can only mention one or two.

Empyema—The great epidemics of 1917 and 1918 afforded unparalleled opportunity for observation and study of the empyema problem. At first early operation was resorted to, that is, while the pneumonia was active, and the mortality was frightful, running as high as 60 per cent. With the change in this feature and by adopting the policy of operating early so far as the empyema was concerned, but late so far as the pneumonia was concerned the mortality was reduced to about 5 or 7 per cent.

Only one other recent advance in chest surgery will be mentioned, and that is Jacobaeus thoracoscopic examination of the chest through a pneumothorax and direct cauterization of the old adhesions, thus permitting of collapse of the lung in tubercular and empyemic conditions. At the recent meeting of the American College of Surgeons, Jacobaeus reported seventy-eight cases of intrathoracic adhesions treated by his method, in fifty-five of which the adhesions were successfully removed and in which 63 per cent of the cases showed pus and sputum rapidly disappearing and the patient becoming symptom free. He further reports several cases of intra-thoracic tumor having been diagnosed by the thoracoscope and afterwards successfully removed by surgical interference.

The Thyroid—Perhaps no other field of surgical endeavor has been more fruitful in recent years than that of surgery of the thyroid. It is now possible to hold out to this class of patients most brilliant prospects of complete recovery, no matter from what type of pathologic thyroid they may be suffering. Radium emanations, protecting the heart with digitalis and hydrotherapy, blood transfusions, open wound for the first twenty-four hours for rapid drainage and metabolic studies, have developed additional factors of safety in thyroid surgery.

Acidosis—The development of the theory of acidosis and its importance in estimated degree of surgical risk is now regarded as of immense value as an adjunct in surgical practice. The incident of acute acidosis during operation is 14 per cent and is more frequent in women than in men. Glucose and soda bicarbonate, administered intravenously during operation, both intravenously and by bowel following operation, together with carbohydrate feeding before and after operation, will entirely prevent or lessen the incident of acidosis. Time forbids any attempt to discuss many other splendid illustrations of wonderful surgical advancement in recent years. Blood transfusion has proven of such inestimable value and its field of usefulness is rapidly broadening. Crile gives transfusions in infections of all kinds. One patient reported was

given 2600 cc. of blood in six hours. In streptococcus hemolyticus in his clinic, recoveries have increased 50 per cent by transfusion. Good results have been obtained in lateral sinus thrombosis and in severe types of exophthalmic goitre.

In conclusion, we remark that undoubtedly the most gratifying feature in these evidences of progress in surgical practice is the contemplation that every advance step means the mitigation of human suffering, the prolongation of life in greater comfort, and the contributing to the sum total of human joy, which after all represent the best rewards and the greatest stimulus to the surgeon for the attainment of the highest possible efficiency in the practice of his chosen profession.

(317-320 Hollingsworth Bldg.).

Hospital Standardization and the Closed Hospital—Since every physician is in favor of anything that will contribute to the better care and treatment of the sick, no argument is necessary to convince the medical profession of the desirability of improving the efficiency of hospital service. The term (standardization of hospitals) is an unfortunate one, since it does not convey in any sense the ends to be accomplished, namely, better care and treatment of the sick. The best criterion of hospital efficiency is the amount of human suffering relieved by the work done in that institution. . . .

Most hospitals are controlled and managed by a board of trustees, and this body is responsible for the policies of the institution. Hospitals are the workshop of physicians; the material worked on is the sick; the output is health. . . . When medical men dominate the policies of the boards of trustees of hospitals, we shall see fewer humiliating instances of medical men selling their soul and body and independence to an institution for the privilege of having their names appear as a member of the staff of the institution.

The closed hospital has come to the front as a result of the propaganda of so-called standardization of hospitals. This sounds much like, and is on a par with, the closed shop of the labor unions. Unless a man is a member of the union, he may not work in a union shop or place.—The American Medical Press.

1922 Death Rate is Higher and Birth Rate Lower—The Department of Commerce announces that provisional mortality figures compiled by the Bureau of the Census for the first quarter of 1922 indicate higher death rates than for the corresponding quarter of 1921. For the States compared the death rate for the first quarter was 13.7 in 1922 against 12.6 for the first quarter of 1921. The highest mortality rate for the quarter is shown for the District of Columbia (17.6) and the lowest for Wyoming (9.6). These early figures forecast for the year 1922 a higher rate for the death registration area than the record low rate (11.7) for the year 1921.

Provisional birth figures compiled by the Bureau of the Census for the first quarter of 1922 indicate lower birth rates than for the corresponding quarter of 1921. For the States compared the total birth rate for the first quarter was 23.3 in 1922 against 25.3 in 1921. The highest birth rate for the quarter (29.2) is shown for North Carolina and the lowest (16.5) for the State of Washington. Higher rates will be necessary for the remaining months of the year if the 1922 rate is to equal the 1921 rate for the birth registration area—24.3.—The Modern Hospital, October, 1922.

THE HEMORRHOID PROBLEM*

A REVIEW

By SOL. HYMAN, M. D., San Francisco

Twenty-five hundred years ago Hippocrates treated piles by cauterization with the hot iron and by ligature, and no advance was made until the introduction of general anesthesia. The ancient methods were then improved, and later Whitehead devised his operation for complete excision of the pile-bearing area, so that today we have the three principal methods of handling piles: ligature, clamp and cautery, and the radical Whitehead procedure.

During the past twenty-five years the fashion with regard to the choice of procedure has changed, but nothing new has been added. At the beginning of this period the German school was dominant, and the clamp and cautery held the field. Then, for a brief period, trained surgeons, seeing the possibilities for a real cure in the excision of the hemorrhoidal plexus, adopted Whitehead's radical operation. But this never could become a general procedure, requiring greater surgical ability than that possessed by the host of practitioners upon whom responsibility for the treatment of piles falls.

Latterly there have come into being specialists for diseases of the rectum and anus, many of whom lack the surgical training necessary for the performance of this often major operation; and practically all of them advocate ligature, either in mass or with dissection of the individual piles, this view being shared by most American surgeons, some reserving the Whitehead operation for the extreme cases with a complete rosette.

Of the three operations at our disposal, which is the best, judged from the standpoints of simplicity, post-operative comfort, and freedom from complications and recurrences?

1. *Simplicity.* The clamp and cautery operation is the simplest, with the ligature method in all of its modifications following as a close second. There is but little to choose between them. Whitehead's procedure, necessitating an accurate dissection and removal of the lower end of the bowel, cannot be reckoned with these from the viewpoint of simplicity.

2. *Post-operative Comfort.* Arthur Neve, in a series of 855 cases, states that, following the ligature operation, many of the patients suffered great pain; following the clamp and cautery operation, practically none. The catheter was used once, on the night of the operation, in about 10 per cent, and subsequently in but two or three of the 855 cases. Anderson reports 300 operations in 18 months from St. Mark's Hospital in London: 150 by ligature, 100 Whitehead, 50 clamp and cautery. Severe post-operative pain was present in none of those operated upon with the clamp and cautery, in 10 per cent of those in which the ligature was used, and in 16 per cent after the Whitehead operation; moderate pain followed these procedures in 30 per cent, 57 per cent and 56 per cent, respectively; and but little pain in 70 per cent, 33 per cent and 28 per cent. The degree of pain was

* Read before the Surgery Section of the State Medical Society Annual Meeting, Yosemite, May, 1922.

measured by the amount of morphine required, little pain requiring none, moderate, one-quarter grain dose, and severe more. In his series the catheter was required in 10 per cent of the ligature cases, 6 per cent of the Whitehead, and none of those where the clamp and cautery was used. The average stay in the hospital was 10 days following the clamp and cautery, 21 following ligature and 26 in the Whitehead cases. Stone, reporting a series of 470 cases operated upon by the method of Whitehead, found that 36 of 146 cases required the catheter, and that the average stay in the hospital has been cut to 10 days.

3. *Post-operative Complications.* Hemorrhage of a noteworthy degree was present in one of Anderson's clamp and cautery, four ligature and two Whitehead cases. In spite of these figures we know that severe post-operative hemorrhage has followed the clamp and cautery operation in many an unpublished case, due to the gaping of the seared edges. Post-operative tags occurred in 6 per cent of the clamp and cautery, 5 per cent of the Whitehead, while 15 per cent of the ligature cases were followed by this annoying sequel. These tags usually require secondary removal to prevent soiling of the underwear, pruritis and burning. They are shrunken external hemorrhoids and are usually produced by the surgeon during dilatation of the sphincter, injection of the local anesthetic or in the course of the operation, and we know no method of preventing their occurrence. One sees them with or without dilatation of the sphincter. That most of them are due to the trauma of the operation itself is undoubted, our experience agreeing fully with that of Anderson. Painful thrombotic external piles, frequently requiring the evacuation of a thrombus to relieve the severe pain, are not uncommon following the ligature operation, and but rare following the clamp and cautery, as is the painful, tender, swollen rosette so often seen about the rectum after the use of the ligature.

Anderson found no abscesses or fistulae to follow the clamp and cautery, and but very few following other methods. Stone gives a list of 10 such cases in his series of Whitehead operations. Sphincter control (Anderson) returned:

Following clamp and cautery on the sixth day.

Following ligature on the tenth day.

Following Whitehead operation on the twelfth day.

Stricture followed in none of the clamp and cautery cases and in 45 of his 150 ligature cases, 5 per cent of them requiring instrumental dilatation up to six weeks following operation. All were cured. Stone reports five strictures in 185 of his Whitehead patients whom he was able to trace. The mortality is negligible, Neve having the only death in 2125 cases reported by four writers.

4. *Recurrences.* Neve notes five known recurrences in 885 cases. Anderson had none by any method, but did not follow his cases over six weeks from the time of operation. During six months, however, he met with but one recurrence after 18 years, in the hundreds of cases presenting themselves at the outpatient department of St. Mark's Hospital. Harvey Stone notes five more or less extensive recurrences in 185 cases followed, many more than one would expect after the radical excision of the hemorrhoidal area. There is no large series of cases reported giving us a basis for judgment concerning the ligature operation.

From the available literature it would seem that the clamp and cautery operation is the operation of choice from the standpoint of simplicity; that it is far and away the best operation in respect to post-operative comfort and freedom from complications, and as good as any judged by the number of recurrences.

In this connection it must be stated that O'Connor reports 500 cases operated upon by the Whitehead method without dilatation of the sphincter, with not one even partial relapse, and with a very comfortable convalescence.

A word should be said concerning the anesthetic. Some of the rectal specialists condemn the clamp and cautery operation as not feasible under local analgesia. I have performed dozens of operations in this manner, and assistants in the hospital have had no difficulty in doing so. In the light of the above figures their statement that the clamp and cautery procedure need only be mentioned to be condemned must be taken with a grain of salt.

In order to circumvent the danger from hemorrhage, really the only weak point, in the clamp and cautery operation, I perform the operation as follows: The individual piles are brought down, following dilatation of the sphincter (general or local anesthesia), and grasped at the base with a heavy, ivory-backed pile clamp, cut and thoroughly seared. Before removing the clamp the mucosa is caught above and close to the clamp with a hemostat. The clamp is now very slowly removed and a suture of fine catgut passed distal to the hemostat and tied above it so as to include the artery of the hemorrhoid which enters the upper third of the nodule. This suture, on a fine needle, is now whipped over the seared edge. This gives as comfortable a convalescence as does the simple clamp and cautery operation and completely relieves the worry concerning hemorrhage. For simple pedunculated piles the ligature is used, and the Whitehead operation is reserved for the extensive rosettes.

Now It Is the Super-Woman Nurse Who Is to Supersede the Doctor—The recommendations of the Rockefeller nursing committee, which organization is trying to gain a foothold in Michigan, and in our estimation ultimately to submerge the medical profession and completely supplant the garden-variety physician by the "super-woman nurse" who is to tell the people when they need medical aid and then call on the doctor for it. Our old German friend, Nietzsche, had nothing on the secretary of the Rockefeller nursing committee for ego.

We note with chagrin that the chairman of the Rockefeller nursing committee, the secretary of same and another member of the committee appear on the letter-head of the American Association for Labor Legislation (the old Health Insurance organization) as members of the administrative council. C. A. E. Winslow is chairman, Josephine Goldmark is secretary, and Miss Mary Beard is a member of the committee. Does it show that our old enemies, the advocates of Compulsory Health Insurance, are playing possum?—Editorial, Illinois Medical Journal, October, 1922.

THE NECESSITY FOR AN IMMEDIATE AND THOROUGH ROENTGENOLOGICAL STUDY OF ALL INJURIES TO THE SPINE*

By HALBERT W. CHAPPEL, A. M., M. D., Los Angeles

Damage to the spine may be by acute injury, chronic strain or by disease, by any two of these, and not infrequently by all three. Quite severe and often completely disabling symptoms sometimes follow very slight trauma. Such cases are really arthritic but with very slight manifestations; or there are congenital variations in the shape of the bones, causing lessened stability which is always a possible source of weakness. On the other hand, this very slight trauma may be sufficient to fracture a transverse process of a vertebra.

As in other parts of the body, the muscles of the back may suffer from simple strain due to hard labor or heavy lifting. The history will often reveal a few weeks at manual labor by a person who had always lived a sedentary life, the chief symptoms being soreness and stiffness of the lower lumbar region, giving only partial disability, and should gradually pass away without any treatment. Sometimes, however, these symptoms persist and the X-ray study shows a congenitally weak back, or arthritic changes.

There is a great difference of opinion as to what really takes place in the sacro-iliac synchondrosis during trauma. As the X-ray does not reveal any definite variation from the normal in the joint itself, the cause must be carefully sought from a study of the neighboring structures, and from a history of repeated traumatism of the lower back. Heavy lifting, frequently assuming the posture of forward body bend and remaining for an appreciable time, thus stretching the ligaments of the sacro-iliac joints, or direct trauma from a fall or blow, will make the joint very susceptible to acute strain or sprain. Take a case of a person stooping quickly to pick up some light article. He has a sudden sharp pain in the joint itself, inability to assume the erect posture, a sensation of something snapping and deviation of the trunk towards the affected side, which are characteristic of acute sacro-iliac strain. The diagnosis can be confirmed by eliciting marked tenderness over the joint on deep pressure, often a fullness over the joint due to fluid in the joint, a positive Kernig's sign, marked spasm of the erector spinae muscles, especially on the affected side, and marked limitation of motion during lateral bending away from the affected side, due to pain and muscle spasm because of a direct pull on the structures forming the joint.

In a more severe type there is an actual slipping forward of the sacrum on the ilium, up to one-fourth of an inch, and this usually happens when there is a congenital variation of the first sacral segment, causing an abnormal sacro-iliac joint, or when there is a sacralization of the fifth lumbar vertebra. When there is a dislocation of the sacro-iliac synchondrosis a stereoscopic X-ray is of value in determining the extent and direction of displacement.

In treating acute strain of the sacro-iliac joint, absolute rest of the joint must be insisted upon. Firm adhesive strapping, and recumbent posture on a non-sagging bed with a small pillow supporting the normal lumbar curve, should give prompt relief from the symptoms. After ten days an effort should be made to turn in bed, and if not painful then there should be freedom in bed for a few days before weight-bearing. A support to the lower back with a tight sacro-iliac strap will limit motion in the joint and prevent a recurrence. If these simple measures fail to give relief at once, then a high plaster of Paris spica will be necessary for about three weeks.

A partial dislocation must be reduced by manipulation under a general anaesthetic, the success of which is usually made known by a sharp sound as the joint regains its normal position. Then it should be treated the same as that outlined for acute sacro-iliac strain. These disabilities often become sub-acute or chronic because of the adhesions that have formed around the joint. Stretching is a most efficient form of treatment, and frequently gives instant and permanent relief.

Damage to the lateral lumbo-sacral joints is often overlooked, both clinically and roentgenologically. The causes are the same as in injury to the sacro-iliac joints, with the very important addition of twisting. The subjective symptoms are higher and more deeply seated. Lumbar lordosis is marked, with the trunk flexed toward the affected side, and with marked muscle spasm on both sides of the lumbar spine. As the joint is deep seated, tenderness cannot be relied upon as a symptom. Movements of the thighs, which are painful in injuries to the sacro-iliac joints, are free and painless. A clear X-ray will detect very slight changes in the lumbo-sacral articulation, and frequently reveals a congenital malformation of the articular facets.

It is not uncommon to find in cases of severe and prolonged backache that one of the articular facets of the lumbo-sacral joints has been fractured, and is surrounded by a large amount of dense callous. For strains or sprains there must be complete and prolonged rest. For fracture of an articular facet there should be complete rest in bed for three months, with some form of rigid jacket, followed by three months of gradually increasing activity and support from the jacket during weight-bearing. It is extremely important to limit callous formation so as to prevent pressure on the adjacent nerve roots, which would always cause pain and sometimes paresis.

Rest is absolutely necessary in all acute lesions of the spine. Massage and active and passive exercises are very detrimental during the acute stages, as they increase the formation of bone

* Read before the Fifty-first Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May 18, 1922, accompanied by twenty-four lantern slides.

callous or scar tissue, which results in a chronic inflammation in or around the joint. Baking and hot compresses may relieve pain and should hasten repair in the bone or soft tissues. Great care should be taken in restoring the patient to normal activity, and this can best be accomplished by graduated exercises and active and passive stretching.

Where there has been an error in diagnosis, and therefore unintelligent treatment, the cases become chronic and suffering is intense. The following cases were selected because a thorough roentgenological study immediately following the injury would have been the only means of arriving at a correct diagnosis:

CASE REPORTS

Case 1—L. A., male, age 56. While lifting heavy sacks of sugar caused an acute right sacro-iliac strain. His symptoms improved only slightly under treatment. No X-rays were taken until four weeks after the accident. They showed the fifth lumbar vertebra to be situated unusually low between the crests of the iliac bones, with a possibility that the transverse process of that vertebra may impinge on either ilium and strain the sacro-iliac ligaments. This condition of the lumbo-sacral spine makes that region much more susceptible to injury. There was also evidence of an hypertrophic arthritis of the lumbar spine. The accident was not the real cause of the discomfort of which he complained four weeks later.

Case 2—J. H., male, age 35. An acute strain of the lower lumbar spine when swinging a sledge hammer, while bending forward with rotation. He was unable to do heavy work three months later, when the first X-rays of the injured region were taken. They revealed a malformation of the fifth lumbar vertebra, but no forward or downward displacement of it. An extra sacral vertebra was also revealed, which with the malformation of the fifth lumbar is a weak place during heavy lifting, and added greatly in producing the strain which will be slow to repair.

Case 3—G. T., female, age 32. Has had repeated attacks of sharp pain, coming on gradually, starting in the right sacro-iliac region, and being slowly transmitted to the right hip and down the right lower extremity. After rest in bed for a few days these attacks entirely subsided. There was never anything unusual that seemed to produce an attack. The first X-rays were taken March 30, 1922, and showed a congenital anomaly in the lumbo-sacral region, that is, a sacralized last vertebra. The transverse process on the right side has all the roentgenological ear-marks of being a lumbar vertebra, while on the left it has the characteristics of a sacral vertebra, and this transverse process also articulates with the top of the sacrum. This condition is a constant strain to the right sacro-iliac joint, and easily produced the symptoms of which she complains.

Case 4—H. F., male, age 44. Had always lived a sedentary life until two months before his alleged injury, during which time he was doing heavy labor. One day following extra heavy lifting his lower back was stiff and quite painful, so that he was unable to continue work. These symptoms have cleared up, but he now complains of pain in the right sacro-iliac region, which is transmitted down the right lower extremity. The first X-ray was taken five months after the injury. This showed a congenital malformation of the last lumbar vertebra, and one which is more prone to strain than is the normal back.

Case 5—M. P., male, age 37. Complains of pain and weakness of the lower back during the past few years, and at times quite severe and with no history of injury to the spine. Recently he has taken long automobile rides, some of them over rough roads. The first X-rays of his spine were taken August 1, 1921, and showed only four lumbar vertebrae, the fifth being sacralized and having all the X-ray appearances of a sacral vertebra. Its position is practically that of the first sacral, producing a congenital anomaly of the sacro-iliac region. This type of spine is mechanically incorrect and therefore much more prone to injury than is the normal back.

Case 6—J. McK., male, age 46. Suffered an injury to the lower back and right sacro-iliac regions when a heavy timber which he was holding suddenly slipped. X-rays which were taken soon after the injury showed an overgrowth of bone connecting the bodies of the fourth and fifth lumbar vertebrae and a congenital anomaly in the lumbo-sacral junction, there being a sixth lumbar vertebra which is situated unusually low between the crests of the iliac bones. The symptoms of acute strain were treated, and his condition grew gradually worse. X-rays taken fourteen months later gave the same findings as above, but, if it had not been for those taken immediately after the injury, it would have been impossible to have properly rated the patient.

Case 7—W. L., male, age 32. While lifting bundles of lumber over his head and tossing them into a truck he felt a sharp pain in the left upper lumbar region, and was unable to continue work. For nearly two and a half years his condition grew worse under various kinds of treatment. One and one-half years after the injury the first X-ray was taken and showed no lesion, but, as it was not clear, another one was immediately taken, which showed a fracture of the left transverse process of the first lumbar vertebra, with separation of the fragments. This was removed, adhesions along the entire spine were actively freed, and two months later he returned to full time work.

Case 8—J. G., male, age 19. Was tossed in a blanket at school and fell several feet, striking on his neck. It has been three years since the accident, and certain twisting movements still cause severe pain which lasts several days. No X-ray was taken until recently, which revealed a slight narrowing of the body of the sixth cervical vertebra, probably caused at the time of his accident. It is a very common site for fractures of the body of the cervical vertebrae; but this could only be definitely proven by comparing with plates made immediately after his injury. After freeing adhesions a full and painless range of motion was restored.

Case 9—B. S., male, age 36. Was struck on the forehead while looking up, and his head was violently thrown back. Since the accident, several months ago, he has been treated actively with no support for the head, his condition gradually growing worse. The first X-ray was then taken and showed that a spicule of bone had been pulled from the lower part of the body of the fifth cervical vertebra—a fracture-sprain. I am presenting the anteroposterior view to prove how easily the lesion could have been missed without a clear lateral view which is so often omitted.

Case 10—M. B., male, age 49. Tripped over a bale of hay and fell about twelve feet, the bale of hay landing on his back. This was followed shortly by total motor and sensory paralysis of the lower extremities, which cleared up during the next few weeks. Now there is pain, stiffness, and marked weakness of the lumbo-sacral region, and inability to move the lower spine. X-rays of the lower spine were taken soon after the accident and were reported negative to fracture and dislocation, but gave evidence of hypertrophic spondylitis. X-rays taken nine months later showed an

increase in the density of the left lumbo-sacral articular facets, due to new bone formation. This overgrowth of bone may be the result of a fracture at the time of the accident and the direct cause of his present discomfort. That is a common site of fracture and one which is frequently overlooked.

Case 11—C. C., male, age 40. Fell from a roof, landing on the top of his head. There was severe pain in the mid-dorsal region, and in the front of the chest. No X-rays were taken, and he was treated for simple back strain, but without improvement. The first X-rays were taken eight months later, and showed a compression fracture of the body of the eleventh dorsal vertebra. A complete study of his spine also showed congenital anomalies, such as a sacralized last lumbar vertebra, the transverse processes having all the characteristics of a sacral vertebra, and a slight sacral spina bifida.

Case 12—J. B., male, age 50. Was struck violently on the top of the head by a piece of rapidly moving casing. He had a sharp pain at about the level of the eleventh and twelfth ribs whenever he moved. No X-rays were taken. He returned to work in two weeks, but gradually grew worse and had to stop. The first X-rays were taken six months later, and showed a comminuted fracture of the body of the eleventh dorsal vertebra, which is wedge-shaped, with a fracture line through the anterior part of the body. An anteroposterior view alone would have failed to reveal the extent of the lesion.

Case 13—J. K., female, age 35. Ten years ago fell forty feet, landing on her feet, and then immediately and forcibly taking a sitting position. There was intense pain in the back, the sensation of formication of both legs and the lower part of the body, and complete flaccid paralysis of the left foot. No X-rays of her spine were taken until recently, which showed an old fracture of the first lumbar vertebra, with some new bone and ankylosis of the spines and laminae of the first and second lumbar vertebrae. Her paralysis is probably due to cord injury of the fourth and fifth lumbar segments, which lie about opposite the first lumbar vertebra.

Case 14—G. S., male, age 51. While sitting on a camp stool lacing his shoe, which was on the running board of his machine, fell suddenly to the ground because the stool collapsed. Pain, spasm and limited motion in the lower back grew gradually worse under treatment for back strain. Two months after the accident an X-ray was taken, and reported negative to any injury of the spine. Eight months later there was not only no improvement, but there were beginning motor and sensory disturbances of the right lower extremity. An X-ray at that time revealed a compression fracture of the body of the fifth lumbar vertebra.

Case 15—S. K., male, age 25. A steeple-jack. Fell fifty feet from a flag pole, landing upright on both feet. An anteroposterior but no lateral X-ray of the spine was taken a few days after the accident and there was no treatment for the spine. On the other hand he was allowed to sit up and twist his body in any direction. Two months later both anteroposterior and lateral views were taken, and showed a crushing of the body and pedicles of the third lumbar vertebra, with displacement forward and a large wedge-shaped piece displaced anteriorly. The body of the fifth lumbar was also crushed, but there was no displacement. Although there were no cord symptoms, he was given rigid treatment for the spine and a most excellent result was obtained.

A careful and complete diagnosis of the above lesions will often make intelligent treatment possible, and will prevent much unnecessary disability and suffering.

THE OUTLOOK IN NEURO-PSYCHIATRY *

By WALTER F. SCHALLER, M. D., San Francisco

It seems fitting for me to address you in this retreat of nature, far away from our practical activities of the consultation-room, hospital and laboratory, not on a technical subject of neuro-psychiatry, but on the expectancy of progress and future knowledge in this, our special field. Each one of us, in the light of new individual experience and accurate observation, is contributing more or less toward this progress and knowledge. Scientific medical advance is not made, however, by leaps and bounds, but by the time-consuming and painstaking recording and interpretation of facts and by their practical application to the problems at hand. Even the trained medical man because of such conservative and sound methods, may not be conscious of, or at least may for the time forget, the steady advance of recent years, so I trust it may not be amiss, before indulging in prophecy, to give a brief retrospect of the neuro-psychiatrical progress in the last two decades.

This period has witnessed a considerable addition to our clinical knowledge by technical tests, and by defining disease syndromes, confirmed by histo-pathologic investigations. Noteworthy is the better understanding of motor disorders; the valuable addition of the pathologic pyramidal tract reflexes; the separation from the spastic pyramidal tract disorders of the plastic rigidities, dystonias and involuntary and associated movements of the corpus striatum group, which has developed particularly from the studies of lenticular degenerations, paralysis agitans, and epidemic encephalitis; and the separation of cerebellar ataxia from the peripheral ataxias by the definition and study of muscle asynergias.

Brain localization, especially as regards the localization of speech, has undergone a very healthful revision by more exact anatomical studies. The discovery of the remarkable autonomy of the divided spinal cord in man has thrown great light on the physiology of the cord and especially on its reflex action and tonus mechanism. The sympathetic nervous system has been the subject of much physiological and clinical investigation, and the close relationship between this part of the nervous system and certain of the glands of internal secretion has been definitely established.

Lumbar puncture and cerebrospinal analysis have become routine diagnostic procedures, without which a neurological diagnosis is at times impossible. Studies of the cerebrospinal fluid circulation have explained the mechanism of hydrocephalus, and suggested a means of its correction. The replacement of the cerebrospinal fluid by air has permitted the exact picturing of the subarachnoid space by pneumograms, thus outlining the ventricular and cisterna cavities. By this method encroachment on these spaces as by tumors may be demonstrated, also the existence of a circula-

* Chairman's Address, Section of Neuro-Psychiatry, California State Medical Society Meeting, Yosemite Valley, May 16, 1922.

tory block. Development of Roentgenological technique, particularly that of stereoscopy, has been a great aid in diagnosis of both general and focal brain and spinal lesions.

Perhaps there has been no greater advance in diagnosis and treatment than in syphilis, inclusive of neuro-syphilis. The discovery of the organism of syphilis and of the syphilitic nature of tabes and paresis, a highly characteristic biological test as a means of diagnosis, a dependable and non-toxic arsenic preparation having curative properties and a means of direct attack upon the infected meninges and adjoining parenchyma in neuro-syphilis by intraspinal treatment, fills a chapter which is one of the most brilliant in all the annals of medicine.

The accurate mechanical determination of blood pressure has led to a much better understanding of cerebral vascular accidents, viz., anemia, thrombosis and hemorrhage. The isolation of the organisms of multiple sclerosis, acute poliomyelitis, and epidemic encephalitis, seems most probable.

In mental pathology we discern a tendency toward investigating basic etiological factors rather than classification along lines of pure symptomatology alone. There has been much light shed on the psychopathic constitutional state by personality analysis, hereditary factors, and a sociological investigation of unfavorable environmental conditions and maladaptations. The role of infections, particularly focal infection, has appeared to explain many cases of confusional psychoses and praecox-like states. The thyrogenous psychoses have been recognized as a type of dysendocrinism.

Mental rating tests have been developed to measure intelligence and have developed into useful diagnostic aids, both in amentia and dementia. Criminological surveys have given us valuable and remarkably constant data, which has interested not alone the medical profession but the custodial, legislative and judicial branches of the law. Indeed, among this latter group is a rapidly growing conception that the problem of the habitual criminal is a medico-psychological and social problem rather than a problem to be solved alone by deterrent term punishment. The psycopathic hospital or ward has become as great a necessity as the general medical and surgical hospital or ward. Psychanalysis as a means of investigating functional nervous states (the functional neuroses) has developed a large following and has found a field of usefulness in diagnosis.

Much light has been shed on the nature of post-traumatic neurotic conditions from the experience with industrial accident cases, and from the experience of the Great War in the so-called shell shock cases. Also much valuable experience has been obtained in these cases by the favorable results of occupational therapy, by healthful and favorable suggestion, and the removal of bad environmental conditions.

Looking back on the rich heritage of the comparatively recent past, one must indeed lack optimism who doubts brilliant progress in the future, as each new advance has opened up large vistas of scientific investigation and research. The anatomy and physiology of the nervous system has yet to be completed, and our knowledge of the sympathetic nervous system is elementary. Further knowledge as regards cellular histology only awaits newer methods. Who can doubt the complexity of the male and female germinal cells, for instance, which from the time of their union have contained all of those elements which go to form ultimately the developed human body, possibly with many characteristics of one or both parents. The protoplasm of such cells must be a very complex and differentiated structure. Scientific research of form and function is as important today as in the past and has equal importance with biochemical research. Pure biology will always be an important aid to medicine along the lines of comparative anatomy, embryology, parasitology, bacteriology and immunology. Animal experiment is absolutely necessary for scientific medical progress. The greatest blow to scientific medicine would be the enactment of anti-vivisection laws.

The problem of the mentally deficient and the psychopathic child or adult is essentially a medical one in its broadest sense. But neither the mental rating tests nor the psychopathic hospital in themselves have solved the problem of these types. The mental rating test is a measure of native intelligence and educational training, but can not measure morality, or general aptitude such as is expressed by personality, responsibility, courage, ambition, persistency and initiative. The psychopathic hospital is a clearing house for the ultimate disposition of its inmates. The disposition of the habitual criminal awaits a practical solution, because his reformation has been given adequate trial and has failed in a formidable percentage. There is a growing sentiment that he should be permanently removed from the society on which he preys because he is bad and dangerous material. Experience has shown this situation also to be true in the habitual drug addict. It is as scientifically possible for human material to be intrinsically poor as it is for inert material to be so. Therefore I believe that birth control from both the standpoint of hygienics and eugenics is only a question of time.

The narrow conception of the sexual theory as a basis of the functional neuroses with psychanalysis as both a diagnostic and therapeutic measure has already broadened to the recognition that other primitive instincts such as self-preservation, fear, and the affective states and mental complexes arising from these may also and to an equal degree engender the psychoneuroses. Experience with the Great War cases showed that the psychoneuroses arose principally from the impossibility of escape from unbearable situations. An evident truth daily becoming more evident is that psychanalysis is by no means synonymous with psycho-therapy, if we are to judge by therapeutic results.

To fully understand abnormal processes a

necessary foundation in normal mental processes would seem to be essential. The scientist, with a mind unbiased by unsupported theory, creed or system of philosophy, cannot dissociate mental processes from brain activity, a physiological activity of brain matter. This conception has lately been given a concrete explanation by Dercum, based on our present knowledge of brain physiology. It is a step forward and serves as a timely and scientific refutation of the absurd conceptions of certain sects whose unthinkable dogma is exactly the opposite: there is no matter, no disease; disease is not material but is the creation of a worldly imperfect and fearful mind.

It is my earnest wish that all of us who are gathered here tonight may live to witness and take part in the progress of neuro-psychiatry in the next two decades. It is our great privilege to be active workers in that branch of medicine representing the highest specialized function of the human organism.

To my way of thinking there can be no greater service to mankind than to contribute towards its betterment, and when one has achieved such a result this must be his highest reward.

(909 Hyde Street.)

Standardizing Human Beings—Governor Miller of New York says that the rising issue in the country is the old issue of State's rights.

Perhaps. But it is very likely that another issue will interpose and demand a prior hearing. This issue will deal with the rights of individuals.

The movement to standardize machinery, mechanical processes and the products of manufacture have been attended, hardly observed, by a movement to standardize human beings. . . .

Laws that interfere with individual rights—rights that are exercised without harming society, neighbors or other individuals—have seldom been enforceable during the entire career of mankind. But such laws have been of service to certain elements the kinds that practice blackmail.

Legislators who aspire to get their names attached to new laws, professional reformers who have carried through a good reform and take up with anything that can be called a reform in order that their incomes shall not be cut off, foolish standardizers and half-cooked societies—these are forcing the revival of an issue as old as the hills. The issue will lead to a definite decision as to what rights an individual may exercise out of his own initiative without respect or reference to the tastes of other people, their prejudices, inherited customs or the standardizing associations to which they belong.—Detroit Journal.

Socialistic Tendencies in Medicine—Socialized medicine can no more succeed than socialized industry has succeeded. Its failure is as sure as its consequences are appalling. There can be no such thing as free dispensaries and free clinics—they are bought and aid for by every member of the community. They are expensive, as is everything conducted by the Government, and the care given by the State to the sick has been and always will be inefficient. Taxpayers have a right to protest against paying medical bills for those who are financially able to defray their own expenses. It is making liars and cheats of a number of people.—James A. Gardner in The American Medical Press.

POSTURE IN ITS RELATION TO NUTRITION *

By ALFRED EDWARD MEYERS, M. D., San Francisco
(From the Department of Pediatrics of the University of California).

It has been only within the last few years that serious attention has been given to the influence of defective posture on the health and efficiency of an individual or vice versa. And yet, one cannot help noticing that practically all malnourished children have atrocious postures.

The question which naturally arises is: "Is bad posture primarily due to malnutrition, or are the ill effects of a defective posture sufficient to contribute toward the condition of malnutrition?" Practically speaking, every child is born with a spine that can be developed to meet the various exigencies of life, and also a normal digestive system. In the case of the breast-fed infant, whose nourishment is sufficient to meet its growing needs, digestion proceeds in a normal manner. But when we consider some of the practices which are in vogue during infancy, the sins of omission as well as commission, it is quite obvious that the posture is at least the first to suffer. The average mother in holding, nursing, carrying, bathing and dressing her month-old infant handles it as if it were a plaster doll, and seems ignorant of the fact that she has much to do in the moulding of its little spinal column. She adds insult to injury when she allows her baby to sleep with a pillow, and often under a weight of covering that causes the child to perspire and holds its legs in the air, flexed at the hips. But perhaps her greatest offense is to make the child sit up or walk before its little muscles are strong enough to support it, and as a result, sooner or later, the little fellow is wearing a brace, or an operation is performed to correct the bow-legs or knock-knees, the result of a parent's lack of knowledge.

If the infant's diet happens to be an artificial one and is properly fed, his digestion probably will not suffer by the lack of attention to his bodily mechanics any more than in the case of the breast-fed child. It is only when the metabolism is upset because of a poorly balanced diet, or later suffers from one of the nutritional disturbances, e. g., scorbutus, pellagra and rickets, that the element of malnutrition comes in and forms a sort of vicious circle:

Rickets: Weak muscles and ligaments, crowding of the lungs, gastro—and enteroptosis, muscle-fatigue, malnutrition.

Muscles and ligaments that are weak fall short in their function of supporting the bony framework, and as a result various ptoses occur. In the condition known as skeletal ptosis, there is a downward displacement of the bones, shown by the drooping of the head, the falling in and down of the chest, and exaggeration of the normal curves of the spine. In visceral ptosis, which is usually associated with skeletal ptosis, there is a downward displacement or crowding of the ab-

* Read before the Fifty-first Annual Meeting of the Medical Society of the State of California, Yosemite Valley, May, 1922.

dominal organs, with unquestionably considerable alteration of function.

There are two periods in the life of a child in which deformities chiefly occur: early childhood, when the upright position is first assumed, and adolescence, when the rapid growth and other changes lessen the stability of the supporting structures. Emerson found that fifty per cent of the children of the Little Wanderers' Home, and seventy per cent of the patients who attended the Children's Outpatient Department of the Massachusetts General Hospital had defective postures. Probably the latter figure shows the real condition as it exists among children, inasmuch as every child who was referred to the Children's Nutritional Clinic of the University of California for underweight showed one or more of the following postural defects:

1. Exaggerated dorsal spine with round shoulders and forward head.
2. Exaggerated lumbar spine with protruding abdomen.
3. Functional and structural scoliosis.
4. Fallen arches or flat-feet.
5. Rickets (flaring ribs, Harrison's Groove).
6. Bow-legs, knock-knees.

Is it not about time that the physician included in his routine examination a closer observation of a child's statics, and not leave it to the realm of the specialists, as we are accustomed to do? It is just as essential, and probably more so, to true up the structural system of a child as it is to true up the various parts of an automobile. A child loses enough energy in a day without adding to it that constantly lost from maladjustment of his body.

What is a correct posture? The ideal posture is one in which all the muscles of the body work in closest harmony, with the least amount of friction, and with the greatest amount of efficiency. All authorities seem to agree that a child, in the assumption of a good posture, must keep his head up, chin level, chest high, shoulder blades flat on the back, abdomen in, back flat, legs straight, toes forward, and weight carried on the forward part of the foot. With such a position a vertical line, dropped from the front of the ear to the forward part of the foot will parallel the axes of the large segments of the body, and seems to coincide with a line which passes vertically through the center of gravity.

It is important to carry the head erect and the chin level because of its direct influence on the spine, chest and shoulders; it also affects the position of the stomach, liver and other abdominal organs, which are suspended secondarily from the neck. A collapsed chest means insufficient space for the organs of the chest to do their work efficiently. Round shoulders mean a decreased rib-cage. Woods-Hutchinson says "that one of the most important factors in the respiratory development and capacity of the human chest is the extent to which the scapuae come to lie upon the posterior wall." A contracted abdomen with its strong muscular walls holds in place the great organs of the trunk, and also aids the circulation of the blood through these organs. Exaggerated curves of the spine affect the diameters of the trunk and alter its proportions. Trunk capacity implies large organs and plenty of room in which they may do their work. Bow-legs and knock-knees put unusual strain on the ligaments, muscles and joints of the body, especially the sacro-iliac. Toeing out is one of the chief causes of flat-feet, due also to abnormal strain on the ligaments of the arch. Carrying the weight too far backward over the heels throws the whole body out of plumb and sacrifices the elasticity of the foot that saves jar in walking. Such a posture guarantees the minimum of muscular action, enlarges the rib-cage, raises the diaphragm, and thus gives to the abdominal viscera its maximum of space for normal functioning.

Incorrect Postures: For practical purposes there are four types of defective posture that need to be considered. The commonest of these is the position of fatigue, because it is the relaxed position which one is liable to assume temporarily when fatigued. The vertical line test shows that there are three main divisions of the body instead of one continuous vertical line as in the normal standing position. The second type of bad posture is one in which the lower part of the back is straight—the small of the back is obliterated. The head and neck are carried forward as in the fatigued position. The third type is the result of over-extension rather than flexion, and results in extreme lordosis. This, in addition to toes out, is the position we all assumed when we were told years ago to stand straight. The fourth type is seen by observing the child from the front or back, and is called lateral deviation or scoliosis. According to various workers scoliosis is present in from 15 to 25 per cent in all children with defective posture.

Factors Contributing to Faulty Posture: Inasmuch as the average person spends more time in sitting than in standing, every child should be taught that, to sit correctly the trunk must be perfectly erect or perhaps inclined slightly forward or backward, and not creased at the waist, which position interferes with the work of the heart, lungs and digestive system. Sliding down in the seat changes the tilt of the pelvis, increases the dorsal curve, and creases the waist. Sitting on one or both feet for any length of time shows its influence on the position of the spine. Prolonged standing, especially in one position, is probably one of the most muscle-tiring of the common everyday acts. The unrelieved strain put on the muscles, ligaments and heart soon leads to a permanent weakening, and as a result broken arches and other postural defects occur, a condition very common among housewives, street car conductors and motormen. The characteristic pose among children of shifting the weight to one foot is the usual outcome of prolonged standing, and in not a few cases is productive of constitutional harm. Walking is one of the best of exercises, especially if the movements of the body

are unimpeded. Every child should be taught that there is a right and a wrong way—that the right way is for the heel to touch the ground first, quickly followed by a transference of the weight to the ball of the foot; and that in bringing the heel down with any great force the elasticity of the step is lost and is replaced by a harmful jar throughout the body. There should always be some mechanical reaction to the movements of the foot or leg, as in the slight swaying of the arms at the side of the body. The same erect posture should be maintained in stair-climbing, a vigorous type of exercise, which stimulates circulation and deep breathing. But care should be taken in not subjecting a child with a potentially weak heart, even though it shows no murmur through the stethoscope, to the rigorous effects of climbing long flights of stairs.

One of the reasons, perhaps, why postural deformity is rare among quadrupeds is that they are free from the distorting influences of conventional dressing. For instance, notice the shirt and coat which are cut so high in the neck behind that they lie like the yoke of a harness across the cervical spine, thrusting the head forward. In addition to this, the wearing of suspenders or pinning the lower garments high up on the undershirt, pulls the shoulders forward, and helps gravity on its downward pull. Even the wearing of low socks, held in place by tight elastics, exerts its influence on posture, to say nothing of the bunions, corns, etc., the inevitable result of high-heeled, pointed-toe shoes.

Many of the common, everyday acts of children which if persisted in contribute their share in deforming the posture. How often we see little children, carrying their smaller brother or sister, who weighs nearly one-half as much as they do; or, as is a common sight among child labor, the poor little fellow who is burdened down with a heavy load steps into manhood with a serious handicap—a static deformity. The carrying of books to and from school probably does more in the establishment of an incorrect posture than any other school requirement. This disfiguring habit can be materially helped by dividing the load, carrying the books on alternate arms on alternate days, or dividing the load at the end of a strap, slung over the shoulders.

Sleep, like nutrition, is fundamental to growth and development. Too little attention is given in the individual home to the atrocious positions which many children assume while sleeping. To lie on the side for hours with the chin resting on the knees is anything but relaxation for the erector spinae muscles. Dr. Fitz says: "The period of sleep is one-half to one-third the growing time of the child, and consequently the pressures and strain of an habitual sleeping posture have an opportunity to influence the growth of the vertebrae and ligaments, and shape them in accordance with their relative position at such time." It is just as essential for a child to change its position during sleep as it is while in the standing position. The factors mainly responsible for a child assuming bad posture in bed are: A poor spring and mattress, high pillows, heavy bed-clothes, cold room, and cold sheets. The simple act of placing a hot-water bag at a child's feet will do much toward making him extend his legs and thus relieve considerable strain.

Relation of Posture to Efficiency: It has been established by statistical tests that physical or mental defect or weakness is in general accompanied by poor posture. The average record of pupils in the poor-posture group has been found to be appreciably lower than the good-posture group in attendance, in department, in physical activity and endurance, in manual training, and in commercial success after leaving school. The army appreciates the value of posture in the training of its soldiers. The exercises, drills, clothing, and sleeping paraphernalia are chosen with this fact always in mind.

Posture as an Expression of Intelligence and Character: The principle that underlies the adage: "Tell me what you eat and I'll tell you what you are" may well be applied to posture: "Show me how you stand and I'll tell you what you amount to." Members of the theatrical profession are the best examples of this fact. It is difficult to picture such men as Sothern and Mantell, in many of their leading roles, assuming anything but their fullest stature, while those with baser parts are always seen in cringing attitudes. The person who would impress, command, or inspire must stand correctly, must look up and not down, forward and not back, while the stooped, grovelling, and hunched-back set are usually the dregs of humanity.

Posture in Its Relation to the Body as a Whole: If we consider the human body to be the most efficient type of machine, why do we not give to it its proper amount of mechanical consideration. The life and efficiency of any machine depends upon the harmonious working of all its members, and just as the whole machine suffers when any one system is not working properly, so do our bodies suffer when they are out of alignment. Not only does the structural framework suffer, but the heart and lungs cannot carry on their normal function in a cavity that is encroached upon; the hampered excursions of the diaphragm, the sagging of the stomach and the colon with interference of their blood-supply, and the pressure of those organs on the kidneys and bladder are the indirect results of a defective posture.

Conditions Secondary to Defective Posture: We are just beginning to appreciate that the examination of a child's posture is as much a part of the diagnostic technique of the pediatrician as it is of the orthopedist. Unquestionably, much of the pathology attributed to focal infections would clear up under postural treatment. Likewise, a large proportion of the growing pains of childhood would doubtless disappear if we paid as much attention to statics as we do to diet. We are very easily convinced that such conditions as backache, legache, footache, painful shoulder, subacute arthritis, and even neuritis might be due to mechanical defects because they are directly referable. Why

is it not possible for conditions to arise that are indirectly due to poor bodily mechanics just as it is possible for a heart to enlarge indirectly from some particular cause? Talbot and Brown have shown that cyclic vomiting is usually the result of a visceroptosis, an accompaniment of poor statics. They have also noted that in such children there is an intolerance for fats. In our work on malnutrition we have observed that many cases of constipation, abdominal pain, poor appetite, and various gastro-intestinal upsets have absolutely disappeared just as soon as the child was taught to stand correctly. As Goldthwaite has shown, the sagging of the stomach and the intestines are sufficient to cause many disarrangements of the liver, pancreas, spleen, kidney and bladder, and rectum. Williams called attention to the prevalence of chlorosis in early adolescence, which he felt was due to tight dressing. Goldthwaite reports that in the examination of the American Expeditionary Forces, many cases diagnosed D. A. H. (deranged action of the heart) cleared up entirely when the patient was taught to stand correctly. Brown has demonstrated a decided decrease in the normal excursion of the diaphragm in patients with faulty postures.

Every case of lordotic or orthostatic albuminuria, which has been diagnosed in the Children's Outpatient Department, with the exception of one, which was complicated by obesity, showed varying degrees of malnutrition, ranging from 5 to 30 per cent under weight for its height, and all showed postural defects, especially in the lumbar curve. This condition was so constant that all cases of malnutrition showing faulty posture, but with no albumin in the urine, were given what might be called a "provocative test" for albumin; that is, were made to stand against the wall in a hyperextended position. This was accomplished by having the heels and head against the wall with a roll about six or eight inches in diameter in back of his lumbar spine. In practically every case it was possible to obtain in about fifteen minutes albumin, ranging from a slightest possible to a definite trace. Because of the frequent association of malnutrition and orthostatic albuminuria, we assumed that the passing of serum albumin in the urine was an important factor in causing, or, at least, maintaining the condition of malnutrition. The fact that the albumin disappeared after the application of a plaster of paris jacket and the child began to gain in weight faster than normally, lends weight to the fact that the so-called "functional albuminuria" deserves more significance than is usually ascribed to it. It may be argued that the rapid gain in weight was due to the change in diet and the correction of the posture, and yet, just as soon as albumin appeared in the urine when the cast became loose, even though it held him in a fairly good position, his rate of gain was appreciably less. Furthermore, when these children were treated from a dietetic standpoint alone, they did not gain, and those treated with braces alone showed a much slower rate of gain than when their diets were also corrected. Children suffering with malnutrition and defective posture, but with no albumin in the urine, responded favorably to this treatment.

Several cases of enuresis have been materially helped after a few visits to the physiotherapy department, one case reporting complete cessation of the habit after four periods. Grover reported rather satisfactory results from the application of hygienic measures in the treatment of enuresis, but if one will examine his principles of treatment he will note: "Nap at noon, no active play after 4 p. m. (with probable rest) and bed at 7 p. m." In other words, by increasing the periods of rest he decreased the periods of bad posture. Even a child's disposition will materially change from the effects of poor statics, causing him to be irritable, nervous, fidgety, and even incorrigible.

The question of mechanical treatment and directions for exercises lies wholly within other provinces, but the prophylaxis of defective posture is the pediatrist's work. Mothers should be taught the do's and don'ts as regards the handling of the child from the moment it enters the world until it leaves the parental fold. Teachers should know the value of good posture and how to help a child obtain it. The child himself should be taught that the maintenance of a good posture is one of the chief "rules of the game."

Physicians and Public Health—If public health is a purchasable commodity how much can a community afford? Some forms of health work some communities cannot afford; the question is to find out what can best be afforded and applied to secure practical results. For example, it would be perfectly possible to raise strawberries in the Arctic Circle, yet it has been estimated that each strawberry so raised would cost $11.40. The abstract theory of raising them there would be proved, but there would be no practical result.

Some foolish people have claimed that public health administration will do away with the need for the medical profession in private practice. Such a development can never come, and any plan, system, or propaganda which indicates that there will be a lessening in the importance of the medical profession as such, is fallacious. However, all public health efforts arising as they do from the practical results of private medical practice, must be based on the confidence, good-will and support of the profession.

Health commissioners cannot be public health despots. Their field is determined by their ability to grapple with concrete problems, and ability to co-operate hand in hand with the profession to which they belong.—George E. Vincent, President of the Rockefeller Foundation.

Though the world know me not, may my thoughts and actions be such as shall keep me friendly with myself. Lift my eyes from the earth and let me not forget the uses of the stars. Forbid that I should judge others, lest I condemn myself. Let me not follow the clamor of the world, but walk calmly in my path. Give me a few friends who will love me for what I am; and keep ever burning before my vagrant steps the kindly light of hope. And though age and infirmity overtake me, and I come not within sight of the castle of my dreams, teach me still to be thankful for life and for times' olden memories that are good and sweet; and may the evening's twilight find me gentle still.—Max Ehrmann.

EDITORIALS

WHO WON AND LOST THE ELECTION?

We are receiving many constructive communications and hearing some few carping comments on the chiropractic and osteopathic majorities at the recent election. Constructive communications are coming from institutions, organizations and representative members of the medical profession who did what they could to defeat the three destructive Initiatives Nos. 16, 20 and 28.

Those who were distinguished by inaction, indifference and lack of co-operation during the campaign are still distinguishing themselves by criticizing those who worked hard and unselfishly to keep the cults from lowering educational standards and removing vital public health safeguards. They are saying now, "Why were we not informed that the chiropractic and osteopathic Initiatives were so serious and we could have defeated them as easily as we defeated anti-vivisection."

Anti-vivisection was defeated by a larger majority on November 7 this year than it was at the general election two years ago. There is a law in California compelling all persons, committees, firms, associations or groups of persons who expend effort and money to influence the action of the electors for or against the adoption of any initiative, referendum measure or constitutional amendment to file in the office of the Secretary of State an itemized statement covering campaign expenses. Against the chiropractic and osteopathic and anti-vivisection Initiatives the only organization to file the statement required by law is the League for the Conservation of Public Health.

Records are therefore available which completely contradict those who try to claim credit for the victory on No. 28 and try to discredit others for the loss on Nos. 16 and 20.

For many months we have been pointing out the probability that the chiropractic and osteopathic measures would be adopted in California because the medical profession in many other States had allowed them to pass without opposition. Many people who have come to California from such States were unable to understand why the medical profession here should oppose cult measures which the medical profession did not oppose "back home."

In the May issue of the Journal we pointed out the serious character of the chiropractic and osteopathic Initiatives and urged all health departments, State, county and city, all hospitals, civic and fraternal organizations, women's clubs, insurance companies and welfare societies as well as all members of the medical profession to oppose actively No. 16, the chiropractic Initiative, and No. 20, the osteopathic Initiative. (No. 28 was not filed at that time but The League was campaigning against the proposed anti-vivisection measure which was filed in June.) We stated in that editorial with prophetic accuracy: "Few voters can spare the time to investigate the extravagant claims made by this aggressive chiro-osteo combination. *If those who are informed neglect to co-operate in broadcasting the facts and exposing the vicious character of these two initiatives, it is probable that quackery will win and create a chaotic condition in the field of medical, hospital and health work.*

The League for the Conservation of Public Health truly assessed the campaign strength of the cultists and informed by letter, by addresses, by interviews, by literature all those who are ostensibly interested in scientific medical practice and progress and public health work. A careful record has been kept of those who did and did not co-operate. This record tells who won and lost the election.

In a broader and truer sense the people of California lost the election and their loss will become apparent in the days to come. All the interest we had in the campaign, all that we did and all that the League for the Conservation of Public Health urged us to do was inspired by the permanent interest we have in maintaining and promoting all the agencies of modern medicine for the benefit of all. How seriously those interests will be affected was pointed out in the leading editorial of the October issue of the Journal entitled "Trafficking with Health."

A cursory glance at the election returns shows that a majority of the voters of certain sections of California preferred the irresponsible misstatements of the exponents of chiropractic and osteopathic colleges to the responsible statements of the President of the University of California, the President of Stanford University, the health officers, hospitals, nurses and others qualified to speak on educational and health subjects.

This revolt against Education as the basis of the scientific practice of the healing art is significant and will undermine all our dependable health agencies unless it is checked.

STANFORD'S MEDICAL MILLION

Stanford University is asking the citizens of California to add one million dollars to the endowment of her medical school and hospitals. They should have the million dollars, and every forward looking citizen should help them to get it. Contributing to an endowment of this character is not charity and it is not a gift; it is an investment in character building, better citizenship, better medicine and better public health, and will pay large and increasing dividends.

For the last several years more than two-thirds of the new licentiates of educated physicians of this State have been recruited by the importation from other States and countries. The normal annual replacement and expansion needs of the State for educated physicians is about four hundred of which the three schools of California supply about 110. We are importers of talent when we should be exporters of talent, as we are exporters

in so many other important lines. Many well prepared young men and women citizens of this State are forced to go elsewhere to get their medical education because of inadequate funds for the expansion of our own schools. This is not only expensive for the students and their families, but in the end it is expensive for the State. Of course, there always will be some of our students who will elect to secure their medical education elsewhere and some physicians from other States always will come to California to live and practice their profession. Both of these movements are necessary and desirable, but it should never be *necessary*, because of lack of facilities, for a Californian to go East to secure his education.

If California is to maintain her recognized place in scientific and intellectual practices and proceedures; if she is desirous of stopping retrogressive tendencies in medical public health and social welfare standards and thus enhance her prestige in other lines, enlarged medical opportunities are essential.

Individuals and small groups of citizens are endowing medical schools in several places in our country. Any one of a number of these schools has received, or is about to receive, more millions from a single person than are asked for from all of us by both the Stanford and the University of California schools. Medical education is expensive. It is constantly becoming more expensive. It is the hardest, most trying, most expensive in the time, energy and money of the student of any of the learned vocations. It cannot be otherwise. The studies constantly grow more difficult and no physician has ever been, or ever will be, over educated. One hundred per cent of them will tell you that they have not had enough. However, when viewed from the standpoint of a great State there are credits of incalculable value constantly being entered against the costs of medical education. The stabilizing influences on public opinion emanating from the faculties and laboratories cannot be expressed in figures but they are tangible to every thinking person. The returns in safety in commerce, quarantine, industry, other professions and home life are more tangible and more appreciated. As a single example the saving to the people of this State by the researches of the two medical school faculties in pointing the way to the olive industry during their recent difficulty, means many millions in dollars and in useful lives saved. The extension and fine service of the teaching hospitals and their various life-comforting and life-saving auxiliaries is known and appreciated by untold thousands of our citizens, who otherwise might be unable to secure all that they required.

The medical profession of the State always has wanted to see San Francisco and Los Angeles as two great medical centers. Our schools are of the best, but they have not been able to expand and become the Meccas they are entitled to be. We ought to be the stopping places as we are the gateways for all the countries and millions of people of the Orient and Far East. For years past, and even at present, they are using us as medical gateways but not enough as stopping places. All we need is endowment and the application of the well known California idea as expressed in other activities and the gateway will be converted into an intellectual, social and even financial harvest. As President Wilbur has said, Stanford's medical mission endowment is the problem of every loyal, forward looking Californian. When the time comes for a similar campaign by the University of California Medical School and hospitals, that also will be our problem. Let us make the gateway lead into California's fertile fields and as East is both directions from this gateway, let us open it straight up.

STUDIES IN CLAY

Barnum's statement about "one being born every minute" is being most exquisitely demonstrated by the use of "beauty clays." The increasing variety, volume and extravagance of the advertisements of the "virtues" of clay and mud as beautifiers of the skin indicates a large volume of profitable business. It takes many sales of dirt, even at ten dollars a pound, to pay for the extensive advertising now being displayed. According to the claims of some of the gentry who deal in clay, this beautifier promises to make Cleopatras of all and sundry and, what is of more interest, it promises to injure the toilet soap business. We have been requested in letters to say something about this fad. There is only one phase of it that is important enough to notice. If we must use clay as a skin beautifier, why don't we use California clay; market it by California business men and thus save all the profits in sales and advertising to our own community? Gentlemen of the Chamber of Commerce, we offer you the opinion that there is a fortune in California clay if you will act quickly before some other "beautifier" is "discovered."

COLLECTION AGENCIES

A number of the members of the California Medical Association have requested that we call editorial attention to this subject. There are undoubtedly perfectly good reliable collection agencies in California handling physicians' accounts. It is also a fact that there are a number who are unreliable and, in certain instances, probably dishonest. Every physician should be extremely careful of the standing of the firm to whom he delivers his accounts for collection. Once these accounts are in the hands of an agency it is exceedingly difficult by process of law either to get the accounts back again or to enforce payment by the agency of fees already collected.

The JOURNAL carries the advertisements of two collection agencies that have been recommended by members of our organization. The JOURNAL would appreciate letters of commendation or criticism regarding any agency engaging in this line of business in this State. Letters will be treated as confidential at the request of the writer.

THE 1923 MEETING OF THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA

Important questions relating to the meeting of the State Society for 1923 have been seriously considered by the Publicity Bureau, the Council and the State Program Committee, in conference with the Section officers of the Society. The outline of the results of these discussions is published on page 411 of the November number of the JOURNAL.

The 1923 meeting will be held in San Francisco, Friday and Saturday, June 22 and 23, preceding the annual meeting of the American Medical Association, Tuesday to Friday, June 25 to 29, also in San Francisco.

The State Society Meeting

1. Meeting of the Council—Thursday evening, June 21, 8 o'clock.
2. General Session of the State Medical Society —Friday morning, June 22, 10 o'clock.
3. Section Meetings (each section to meet separately)—Friday afternoon, June 22, 2:30 o'clock.
4. Meeting of the House of Delegates and Meeting of the Council with Officers of County Societies and Section Officers—Friday evening, June 22, at dinner. This meeting to continue until all business of the House of Delegates has been transacted.
5. General Meeting (the League for the Conservation of Public Health)—Saturday morning, June 23, 10 o'clock.
6. Meeting of the House of Delegates—Saturday afternoon, June 23, 2:30 o'clock.
7. Meeting of the Council—Saturday evening, June 23, at dinner.

The State Program Committee, in conference with the officers of the various sections, decided at their meeting on September 9, 1922, that each Section of the State Society should hold one meeting, on Friday afternoon, June 22. At this meeting there is to be read, by title only, as full a program as the officers of each Section care to accept. At this meeting also will be transacted the usual business of each Section, such as election of officers, resolutions and other problems. The rest of the time of the meeting may be taken up by the full presentation and discussion of such leading papers as the Section officers may select for that purpose.

The State Program Committee will arrange the program for the General Meeting of the State Society on Friday morning, and the League for the Conservation of Public Health for the meeting on Saturday morning.

The State Program Committee wishes to announce at this time that the final program will go to press on March 15 and will appear complete in the April issue of the JOURNAL.

All persons desiring to present papers by title and for subsequent publication in the JOURNAL as having been read at this meeting of the Medical Society should communicate promptly with the officers of their particular Section, and the officers of all of these Sections (of which there is a directory in every number of the JOURNAL) undoubtedly will communicate with members of their Sections, in order to arrange for as satisfactory a program as possible.

The State Program Committee does not place a limit upon the number of papers which may be presented by title to each Section. The Section officers will determine the number and qualifications of the papers presented to the Section by title, and they will also determine what papers and how many will be presented in full at the one meeting of each Section. The editor of the JOURNAL announces that about 160 Section papers of 4000 words or less each can be used between the 1923 and 1924 meetings of the Society. This in addition to papers of the general sessions and some read before county societies will take all of the available space of the present enlarged JOURNAL for one year.

Office headquarters for this meeting, as well as for the American Medical Association meeting, will be in the Balboa Building. The Palace Hotel has been designated headquarters hotel for the A. M. A. meeting, and will be considered hotel headquarters for the State meeting. The place of the general meetings and the Section meetings of the State Society will be announced later.

PHYSICIANS' BIOGRAPHICAL RECORDS

The office of the State Society is making an effort to improve the biographical records of our members and of all physicians in the State of California. Worthwhile data has been accumulated in very large amount both through co-operation with the physicians themselves and through the press clipping bureaus.

Among other things we would like to have would be reprints of all articles published by our members. If every member will mail now a reprint of articles he has published heretofore, and in the future of each article as it appears, these reprints will be filed in his personal record folder. All physicians, therefore, interested in having their records complete are requested to send to the secretary reprints of such articles as they have published and to put the secretary of the State Society on the mailing list for reprints of all future articles. Reprints of articles by members of the State Society will be acknowledged in the JOURNAL.

JUVENILE DELINQUENCY INCREASING

The Police Department of San Francisco recently gave out some statistics showing a decided increase in the juvenile delinquency in the city. It is reported that arrests among boys and girls, from ten to twenty-one years of age, average eight or nine a day. Thirteen per cent of the criminals in San Quentin Penitentiary are under the age of twenty-one. If these statistics are accurate, and there is no reason to question them, it is time for physicians, public health officers and other citizens interested in better health and better home conditions to seriously consider the cause of this situation. It would also be very interesting to know what the general situation is throughout the State and whether or not juvenile delinquency and crime is increasing only in certain cities or in rural communities as well.

INDEX FOR THE CALIFORNIA STATE JOURNAL OF MEDICINE FOR 1922, VOL. XX.

With the endorsement of the Publicity Bureau, this index is prepared along the lines used in the Index Medicus, the Library of the Surgeon-General's office in Washington, and the Journal of the A. M. A. With an author index of this character, it is easy, by consulting subsequent editions, to establish the bibliographical record of any of our members, and this will become exceedingly useful in the years to come.

This volume of the Journal has not been indexed by subject for the following important reasons: a subject index is expensive to prepare and to publish. It ought not to be necessary because of the very thorough and complete indexes contained monthly in the Index Medicus and issued quarterly by the A. M. A. in the Quarterly Cumulative Index to Current Medical Literature. This latter publication constitutes one of the extremely valuable services of our national organization. The four volumes, issued every year, give the index to all worthwhile medical literature from all journals in the world. It is well done and the subscription price is nominal.

On the Treatment of Syphilis With Bismuth Salts—Sazerac and Levaditi of the Pasteur Institute, Paris, have recently proposed the use of tartrobismuthate of potassium and sodium, containing approximately 50 per cent of bismuth, for the treatment of syphilis. In their preliminary work on rabbits (infected with Spirochaeta pallida and S. cuniculi) they found that the only safe and efficient method of administration was by the subcutaneous or intramuscular route. Intravenous injections were shown to be dangerous on account of the markedly toxic action of the drug. In order to decrease this danger as far as possible they substituted a suspension in oil of the drug for the watery solution. This was found to be the method of choice in the treatment of human cases on account of increased tolerance and less local reaction.

Fournier and Guenot have tested the value of this treatment of syphilis on a comparatively large scale and report the results of the treatment in about 200 cases.

In cases of primary sores the treponema disappeared as a rule after the second injection; in some cases even after the first. The small erosive chancres healed completely in a few days; the medium sized chancres in one to two weeks. The large or ulcerative chancres persisted about three weeks, but they lost rapidly their specific characters and soon appeared as ordinary lesions, the time of healing depending on the size of the individual ulcer.

The local induration and the adenopathy were influenced more rapidly by bismuth than by any other treatment and disappeared often completely within a few weeks. In no cases where the treatment was regular did secondaries appear. The Wassermann reaction became negative and remained so for the period of observation.

"In cases of secondary syphilis the mucous patches disappeared after the first or second injection. The hypertrophic patches dried up in a few days, faded and were reabsorbed in ten to twenty-five days, according to the amount of new tissue formation. If the treatment was commenced during the appearance of the roseolar rash this was arrested in its development, sometimes after an exacerbation of twenty-four hours. Herxheimer's reaction might also appear near the papular syphilides. The simple roseolar rash usually disappeared in five or ten days; the papules took a little longer to be absorbed. The authors have seen a generalized miliary eruption and palmar syphilides, manifestations which, as is well known, are rebellious to specific treatment, disappear in two weeks.

The general secondary manifestations—headache, bone pains, etc.—always yielded to the first injection.

The authors mention eight cases which had not yielded to arsenical and mercurial treatment, but which readily responded to the bismuth treatment. They also had a case of acute syphilitic meningitis with all the characteristic symptoms. After four injections the clinical improvement was complete. After two weeks of treatment the lymphocytes in the spinal fluid had been reduced from 400 to 7 per cubic millimeter.

Lesions of tertiary syphilis, bumata, osteoperiostitis and ulcers yielded, as a rule, very rapidly to treatment. In cases of visceral and nervous lesions the time allotted to treatment has been too short to enable the authors to express an opinion.

After the first two or three injections of 0.20 gram, a bi-weekly injection of 0.30 gram seems to be good practice. Two to three grams should be injected during a month.

After the first series of injections the treatment could be continued with a single weekly injection of 0.20 to 0.30 gram, or be suspended for a month to be recommenced again in the same manner as described above.

One should follow the progress of the treatment by repeated examinations of the blood and check up every case at subsequent regular intervals.

With regard to untoward effects of this treatment the authors state that they have given over 1500 injections without having experienced any really important mishap.

In cases of grave visceral lesions, and especially where the renal function is impaired, one should proceed with caution. A slight elevation of the temperature was seen in some cases the day after injection, accompanied with pain in the back, but no general reaction was observed. After the first four injections a moderate polyuria occurred in a few instances. The only two manifestations that might cause some trouble are local reactions and the stomatitis. The former were seen in a few patients who walked too much immediately after the treatment. The tendency to stomatitis can be very well controlled by hygienic measures of the mouth. In a few cases dark spots of bismuth impregnation were seen on the mucous membrane of the mouth.

The bismuth has been recovered from the blood and cerebrospinal fluid and has been shown to be eliminated through the saliva, bile, feces, sweat and urine.

The authors state that bismuth undoubtedly is a most energetic anti-syphilitic agent, having particularly marked effect not only on the infectious manifestations of the disease, but also on the Wassermann reaction. They conclude, however, that time only will tell if this drug will prove to be of value in the radical cure of syphilis.—United States Naval Medical Bulletin.

CORRECTION

In the article on "Intra Vitam Bone Marrow Puncture in Pernicious Anemia," by Falconer and Morris (published in the November Journal), the statement was inadvertently omitted by the authors that the work was from the Medical Department

IS SUBSIDY CONTROL OF MEDICAL EDUCATION A MENACE?

Surgery, Gynecology and Obstetrics recently published the address of Dr. John B. Deaver, delivered before the College of Surgeons. He said: "We who are doing the world's work must see to it that our influence in this respect is not usurped by those who sit at their desks and think out specious arguments, fortified by vast financial power placed at their disposal by well-meaning men who are not themselves qualified to judge in this sphere, but must be guided by advisers who are not always infallible. I am thinking of the recent furore in favor of the full-time teacher in clinical branches. I am musing over the creation of great clinicians overnight by the feat of powerful influence. I am impressed by the rapid metamorphosis of the fledgling, nurtured, shielded, not to say mentally confined within the limits of sympathetic institutions and departments. I am not questioning the motives of the originators of this audacious movement, but I am watching for its results—not too brilliant thus far and promising less. I am concerned for the students, and would be alarmed for the profession were it not for my great confidence in the sober sense of that great body of a democracy such as this, which will eventually work its way towards its own proper method of dealing safely and sanely with conditions. Still I marvel at that new super-intelligence, which in rapid pursuit of its ideal, sets aside the principle of natural selection, the well-proved motive of human endeavor (high reward) and the cardinal virtue for the attainment of practical results—experience. In my heart I am thankful that such men had no voice in the selection of a generalissimo for the allied armies, and I note with curious reflection that the vast resources upon which the idea floats were not obtained and are not conserved by similar fancies.

"During the last five years, as you know, the tendency has been toward the full-time clinical teacher. Its central idea was good, but its application, begun before the war, if I mistake not, was influenced by the German idea of efficiency, which, as you all know, failed utterly to include the human element in its equation. Without wishing to appear reactionary, but with the interest of the profession in mind, I do not hesitate to say that I doubt the wisdom of the present course. It is an extreme, and the pendulum must soon swing in the opposite direction. The professor of clinical branches should not only be allowed, he should be obliged, to be in direct professional contact with the public. The science and art of surgery are one and inseparable. There can be no art that is not based on science, and there is no science without its practical application. Of the chaste union of the two shall spring the fruit of the tree of life for the untold millions, born and unborn, whose lives and whose happiness shall depend upon sane surgical science and safe surgical skill. Science has been kept sane only by constant contact with observed and demonstrable facts, like the giant who renewed his strength by contact with mother earth. Practice is kept sane and free from danger of the rule of thumb only by a constant infusion of science. The problem of today is to avoid conflict between these essential elements of a real union, to provide for their proper function, to inculcate into the minds of the young the true conception of their relations and responsibilities, and to deliver to society the greatest good to the greatest number. The last consideration is the most momentous one, for it means results, and it is by results that we shall justly be judged.

"We must deplore, therefore, anything which detracts from that high standard of service to the community which the community has a right to demand, in view of the extraordinary freedom and power which it has conferred upon us. It is our profound belief that the system of full-time salaried chairs for the clinical branches which has been forced upon a number of our foremost institutions by powerful influences is not only contrary to the spirit of American institutions, and contrary to the proper workings of the human mind, but that it is sure to result in degeneration of that art which is the true flower of science, and in the deterioration of the instruction to the student in how to deal effectively with the problems which he must confront in his chosen life work. To me the plan smells of the midnight oil of the theorist (to say nothing of the oil which has lubricated the ways for its launching). It has in it none of the red blood of the real administrator working to get results with humanity as God made humanity. In its application as I have witnessed it the plan shows no appreciation of the fact that the head of a clinical chair must be a clinician. Is not the clinical art also a science? Does it not rest upon knowledge and does it not depend upon aptitude, ability, experience and hard work? Can anyone become a clinician by merely calling himself by that name? Does appointment to a professional chair make him a teacher? Or is it no longer true that in addition to knowledge, which is not so common a possession, the successful department head must have qualities of personal integrity, stimulating personality, and administrative ability?

"In attempting to remedy the evil of the clinical professor overloaded with private practice and neglecting his teaching, his department, and his scientific work, these men of admirable intentions have gone to an equally unjust extreme. Orderly evolution was going on, even rapidly, if one considers world movements; but it apparently was not rapid enough for those who seek to reach the heights in a bound. But this is the day when the professor may try his theories on the whole human race, and the Pied Piper of Hamelin has his counterpart in Russia and would-be imitators everywhere.

"If I mistake not, there are signs of returning sanity. The domination of those who have shown their inadequate grasp of the whole problem is being loosened. Let us hope that the education of our youth will be entrusted to men who are outstanding figures in the field which they are presenting to the impressionable mind. Let us all fully realize that science is the beginning of practice, and that practice is the goal of science."

THE GORGAS MEMORIAL FUND

At the St. Louis annual session the Board of Trustees reported to the House of Delegates that in response to a request received from the directors of the Gorgas Memorial Institute of Tropical and Preventive Medicine for the co-operation of the American Medical Association, the Board had taken action which resulted in the appointment of a committee, representing the American Medical Association, to act on the project. The following were appointed: Charles W. Richardson, Washington, D. C.; Fred B. Lund, Boston, and George E. de Schweinitz, Philadelphia.

The House of Delegates unqualifiedly endorsed the Gorgas Memorial as a tribute to a past president of the Association and one of its most distinguished and loved members. At its recent meeting the executive committee of the Board of Trustees received the following statement from the committee and directed its publication:

Statement and Appeal for Co-operation

As a result of the stimulating suggestion of President Porras of Panama, it has been resolved that a fitting memorial shall mark the humanitarian service of the late Major General William C. Gorgas, and the beneficent influence of his life and work on mankind throughout the world. Following the thought of President Porras, it has further been decided that this memorial shall take the

form of a scientific institute for the study of tropical diseases and of preventive medicine.

No better place could have been selected than Panama City, the gateway between the Atlantic and the Pacific, where General Gorgas' well-planned and executed work made possible the building of the Panama Canal.

It is hardly necessary to call the attention of the medical profession to the far-reaching effects of General Gorgas' work on the welfare of the people of the whole world, especially in tropical and semi-tropical climates, and in all places subject to the inroads of infectious disease.

We of the medical profession remember him as our Surgeon-General during the early part of the World War. We remember his prompt recognition of the necessity of bringing into active service large numbers of physicians and surgeons from civilian life. We remember his genial and kindly nature, his high character, and his steadfast effort directed toward the organization and equipment of the Medical Corps of the Army. We remember the patriotic response. We remember him as a great sanitary officer, to whom we wish to pay a lasting tribute.

A central committee has been formed, with Admiral Braisted, retired, ex-president of the American Medical Association, as its president. The American Medical Association has appointed a committee of three to work in accord with the central committee, and through its members this appeal is made to the American medical profession.

The plan is to build at Panama an institute for the study of tropical and infectious diseases, with a hospital, laboratories, departments for research and all other facilities required in an institute of this character, erected and administered according to the most progressive, modern ideals. The Panamanian Government, owing to the far-sighted, philanthropic vision of President Porras, has donated the great Santo Tomas Hospital, and also the ground on which it is proposed immediately to construct the buildings as they have been described. Dr. Strong has been appointed the scientific director.

In conjunction with this work in Panama, there will be established in Tuscaloosa, Ala., the Gorgas School of Sanitation for the purpose of training country health workers, sanitary engineers, and public health nurses, especially educated to deal with the problems peculiar to the Southern States.

An endowment of six and one-half million dollars will be required to enable the institute to carry on the work according to the plans which have been formed.

The Republic of Panama has demonstrated its sympathetic and practical interest in this enterprise with splendid liberality. The physicians of our country, and especially the members of the American Medical Association, surely will not disregard the memory of a former president, and will seize the opportunity to make in this respect a contribution of which they will be proud.

The campaign for funds is to be international. A large response is expected from North, Central and South America, since the nations of these countries have been the chief beneficiaries of the labors of General Gorgas. It is fitting that his co-workers of the American medical profession should be requested to respond generously to this appeal. It is hoped that every member of the American Medical Association will make as liberal a subscription as possible. Any sum will be gratefully received. Checks should be drawn to the order of the "Gorgas Fund" and should be mailed to the American Medical Association, 535 North Dearborn street, Chicago.

CHARLES W. RICHARDSON, Chairman,
Washington, D. C.,
F. B. LUND, Boston,
G. E. DeSCHWEINITZ, Philadelphia.

THE PUBLIC PRESS AND THE PHYSICIANS

It is interesting and instructive for physicians to note what the public is thinking and saying, particularly as appears in editorial comment by important newspapers. A meeting of the A. M. A. in St. Louis was the occasion for considerable amount of newspaper discussion of physicians and medical affairs from which we quote a few extracts.

The St. Louis Post Dispatch says: "A transition from individual to organized practice already has begun, and that the movement is rapidly spreading. This means that the progressive leaders recognize the profession's obligation to the public in fighting disease, regardless of the effect on private practice. They regard the benefits of medicine as belonging to humanity and not to the doctors. . . . With the profession under such leadership as Dr. de Schweinitz and his supporters, the public will feel no misgiving toward the organization of men who, more than any other group of equal number, hold in their hands the power of human life and death. The public, moreover, should ally itself with this organization to stamp out quackery and drive from the profession elements that would exploit the people rather than assist them to health. It can do this by fighting such measures as that put over by the last Missouri Legislature to grant physicians' licenses to applicants who pass a State examination, regardless of their education and training."

The Globe-Democrat prints the following: "Doctors are our modern father confessors. Men and women go to them who formerly went to the clergy. They have earned and they have received the confidence of all who are in trouble about their bodies, and of many who are in trouble about their souls. No one can speak too gratefully of the way in which the work is done, of the skill, the kindness, the understanding and sympathy, even the toleration of human weakness on the part of the medical profession. Nevertheless, I put this question: Does the medical profession as a whole take its proper part in guiding and influencing public opinion in these matters wherein it alone can speak with authority?"

Under such headings as "The Family Doctor," "Too Many Specialists," "G. P.'s and Specialists," editors over the country plead for the return of the "all 'round family doctor" or defend the development of specialization in medicine, according to their several viewpoints.

The Denver Times wants the old-time general practitioner and family doctor restored to the place which he once occupied in the esteem and affections of the public. "Specialization has run riot in medicine during the last ten years," says the Times, and "it is time for the old family doctor to return, the physician who was not only well grounded in medical knowledge and trained in the school of varied experience, but possessed of common sense and genuine humane sympathy." The editor of the Western paper, a very smooth writer and a hard hitter, insists that "versatility in medicine is much to be desired," and thinks that specialists are inclined to be "single trackers," who know little outside of their especial fields. Admitting that specialists have done much to improve technique and to advance the cause of medicine, the Denver editor decries the growth of specialism and says "the present tendency carried to its logical conclusion, means that every man must employ a corps of specialists to look after the health of his family. It is fast coming to this unless steps are taken to develop the general practitioner anew and to stop the influences which have weakened confidence in his judgment and ability."

The Hartford Times is for the specialist and for the general practitioner, too, with an apparent leaning toward specialization as offering more than can otherwise be had for the public benefit. "The old-time family physician," who let the children play with his watch chain and who gave them enormous

doses of calomel and whisky and quinine for almost anything, "got away with it," but knew surprisingly little about the human body. On the other hand, he often knew more about the human soul than does the learned specialist of today, and was able to boom his patient back to health by sheer force of personality. Just as many times, however, he was unable to function at all and was pitiably helpless in situations which today seem relatively simple to the medical man. There cannot be too much specialization in medicine and, just as truly, there cannot be too much of the friendly sympathy of the old-time family physician. . . .

The Fall River Globe defines State medicine as "any form of medical treatment provided by the Federal, State, county or city government." The Globe makes it clear that the doctors do not oppose State control of communicable disease, nor treatment and care of the indigent and the insane, nor preventive measures initiated by the State for public health, and then agrees that "there is, as the doctors maintain, too much of a disposition on the part of the State to take up work with which it should have nothing to do in an active way. And as the doctors declare, the State's paternalism is sure to result in community irresponsibility." . . .

The Courier opines that the "continual, constant coddling, nursing and babying of the individual by the group is the most dangerous tendency in American public life of today. We are making weaklings out of individuals, undermining the national character, taking away the need or necessity for self-reliance, and teaching old and young to believe that it is somebody else's job to look after us."—Abstract from American Medical Bulletin.

Nutrition in Schoolchildren—Taliaferro Clark, Washington, D. C. (Journal A. M. A., August 12, 1922), reviews this subject on the basis of previous reports made by others, and points out that nutrition is a matter of general education and of change in community custom and habit, involving time, and of State and Federal guidance. It is not merely a question of weighing and measuring. So serious are the demands made on the time of both pupils and teachers by those engaged in, or wishing to engage in, sundry forms of welfare work, and by others with newly devised schemes for the general uplift which they wish first to try out in the schools, that any great extension of such activities, it seems, will leave but little time for instructions in the three R's. It is for this reason that all basically related forms of school health work should be united and harmoniously fitted to the general plan of health instruction and health supervision, utilizing the combined wisdom of both the educational and health authorities for such purpose. Courses in health should be prescribed and given weight in the school curriculum corresponding to major subjects. Such instruction naturally should be adapted to the intellectual capacity of the different age groups. As regards nutrition, teaching in the early grades should be concerned more with the importance of milk, vegetables, fruits, cereals and the like, in the diet, from the standpoint that they help to make the child grow up to be strong. The teaching of the principles of nutrition and nutritive values should be reserved for the older grades. Instruction in nutrition should not be reserved for and given only to a special group of children, either underweight or otherwise, but should include all children attending school. Special nutrition classes for malnourished children are unnecessary in a well-conducted school system providing proper health supervision. Weighing and measuring should be considered a necessary measure in every physical examination, and, in the case of children who fail to gain or lose weight steadily, the causes should be investigated and corrected. The character of the school lunch should receive careful attention, especially in rural schools, where many children frequently come long distances after a hurried breakfast, bringing a hastily prepared, poorly selected lunch, or none at all, and remain all day. Aside from the question of the effect on health, an underfed child is no more fit for mental effort than is the laborer for physical tasks. Clark also calls attention to the apathetic, and, in many instances, indifferent attitude of the medical profession to the danger signals that have been so prominently brought to the front by the lay workers, and urges the importance of physicians displaying more active interest in nutritional problems and giving more hearty support and co-operation in solving them.

Nursing Education in Michigan—In Michigan the battle wages merrily as to whether the University shall establish a separate department of nursing which shall be entirely independent of the medical profession. The Journal of the Michigan State Medical Society says that some of the self-appointed leaders in the nursing profession, in discussing the subject, have said, "We are not going to take orders from the doctors, and henceforth we will perform our nursing service under our own direction and not under the direction of the doctor." As we understand the plan, which, by the way, has been proposed by the Rockefeller Foundation with a one-million-dollar endowment as the bait to bring about acceptance, the University is to have a department of nursing, which is just as distinct a department as is the department of medicine or law, and it is to operate independent of any other department. The final product turned out by this department is to be a "super-nurse," or one who is supposed to possess knowledge greatly in excess of the knowledge possessed by the ordinary trained nurse who has had the advantage of contact with patients and members of the medical profession, though the super-nurse is not required to have any such fundamental knowledge.

As has so well been stated by leading medical men and medical publications in this country, there is little need for "super-nurses," and certainly no need for the fifty thousand proposed by the Rockefeller Foundation.—Editorial, Indiana State Medical Journal, October 15, 1922.

Extension Lecture Service in Physiotherapy—By co-operation between the California Association of Physiotherapists and the Section officers of the State Medical Society, the following extension program will be available any time after January 1, 1923, for county society meetings:

1. The Correction of Static Deformities by Exercise—H. H. Markel, M. D., (with moving pictures).
2. The Mechanics of Posture and the Posture Examination—Sarah R. Davis.
3. Physiotherapy in the Treatment of Heart Diseases of Children—Edith Bronson, M. D.
4. Physiotherapy in Back Injuries—E. W. Cleary, M. D.

THE NOSTRUM AND THE PUBLIC HEALTH AND TRUTH IN ADVERTISING DRUG PRODUCTS

The American Medical Association, through its Propaganda Department, is continuing the splendid work in exposing nostrums that are being advertised and sold to the public. The Journal is in receipt recently of four new publications of this department: "The Nostrum and the Public Health and Truth in Advertising Drug Products"; "Obesity Cures"; Epilepsy "Cures" and "Treatment"; "Female Weakness Cures."

Arthur J. Cramp, Director of the Propaganda Department, in opening a discussion of The Nostrum and the Public Health, says: "Broadly speaking, the nostrum belongs in one of two general classes; one class comprises those unscientific mixtures that are advertised primarily to the medical profession, and first reach the public by way of the prescription; the other class includes those mixtures that are sold direct to the public. Nostrums in the first class are sometimes spoken of as 'proprietaries'; those in the second class are colloquially known as 'patent medicines.' The public suffers from both classes, the only difference being that in the case of the former the physician has to share the responsibility with the nostrum exploiter. There is no clearly defined line of demarkation between these two classes. Many of the 'patent medicines' of today were the 'proprietaries' of yesterday. Shrewd manufacturers—or, more correctly, exploiters, for many of these products are not manufactured by those that sell them—discovered years ago that one of the least expensive methods of introducing a nostrum to the public was by way of the medical profession. After the profession had been widely circularized and much space bought in the advertising pages of medical journals of a certain type; after uncritical or unthinking physicians had prescribed the products (of course in the 'original package' with the name blown in the bottle or a monogram stamped on the tablet); after the patient had learned with disgust that his physician had merely prescribed a 'patent medicine' that could more cheaply have been purchased direct—then the one-time 'proprietary' threw off its 'ethical' mask and became frankly a 'patent medicine.' Such has been the genesis of many a 'patent medicine' on the market today. Others, less deviously, have gone directly to the public at the outset."

Cramp classifies advertised drug products in four groups:

Group 1. Non-proprietary pharmaceuticals; official or semi-official in character.

Group 2. Scientific proprietary products advertised to the medical profession for prescribing and dispensing purposes.

Group 3. Unscientific proprietary products nominally advertised to the medical profession for prescribing and dispensing purposes.

Group 4. Proprietary products advertised to the public as home remedies for the self-treatment of disease; colloquially, "patent medicines."

The article explains in an interesting and informative way the abuses of public confidence that freely happen in advertising these products. The preliminary article is summarized by Cramp as follows: "Summed up, it may be said that the advertising of non-proprietary drug products is invariably truthful and conservative; the advertising of scientific proprietary drug products sold for prescription purposes only also, in general, conforms to the truth, with occasional lapses due to overenthusiastic copywriters. The advertising of unscientific proprietary products offered nominally to the medical profession, but virtually to the public, is invariably exaggerated and misleading and, in some instances at least, fraudulent. The advertising of proprietary products offered directly to the public, that is, of so-called 'patent medicines,' is notorious for its untruthfulness, not alone in its declaration, but also in its inference."

It is part of the duty of a conscientious physician to know what his patients are taking and doing that is not prescribed by him. Careful reading of pamphlets put out by the Propaganda Department will be of use in this respect, and will also enable the physician to discuss intelligently with his friends the meaning of some of the new methods of advertising.

Disgusting Propaganda About Tooth Pastes—We take this opportunity to announce the arrival of another cure-all tooth paste. We are requested to prescribe it to our patients, and are informed by the dapper distributor of samples that he, as well as the president of the company, believes that this particular paste will add to the calcium content of enamel. No mastication, no insalivation, no digestion, no assimilation, nor metabolic changes of the good old sort, whatever, are required. Like a sponge, the enamel of the tooth just naturally soaks up the calcium contained in the paste (this action being simplified, of course, by the fact that the enamel of the tooth is only about 98 per cent inorganic matter), and builds the free calcium into the tooth structure with the same expediency with which a swallow builds a mud nest under the eaves of one's barn.

Viewed from the standpoint of our present knowledge, it would seem as probable that one's flatiron could absorb starch, and then relinquish it in sufficient quantities to starch one's shirt while it is being ironed (that is, of course, providing one wears such a garment), as it would be for the enamel of a tooth to take up calcium from a tooth paste in the mouth, and store it away for the purpose of resisting decay at some future time.

Besides all this the preparation is a "delightfully refreshing dentifrice" (which is rather wholesome information, all things considered), "remarkable for the quickness with which it removes film and tartar."

This available supply of calcium is supposed to prevent tooth decay "which is a process of decalcification." Just how this replenishment of calcium is brought about we do not know, unless the bacteria involved in tooth decay get loosed in the presence of the calcium and become primarily builders, instead of destroyers, of tissue, which would bring them under the category of trained animals, establishing thereby a precedent for bacterial metamorphosis.

We, as dentists, are urged to prescribe this preparation to our patients with apparently the same reckless abandon that is employed by a high school girl when ordering soda-fountain beverages, thereby spreading a propaganda that seems to have been put out wholly and purposely to increase sales rather than to be based on any unusual merit of the preparation.

We hope that the day is far distant when we will be convinced that the human mouth has degenerated its functional activity until it has become a chemical laboratory or experiment station for the sole purpose of expediting the action of tooth pastes and their consequent exploitation as well. Should this unhappy condition ever exist, we will gladly call upon our surgeon to construct for us another mouth, perhaps on the back of our head (where so many mouths would look better anyway), and we will cheerfully vacate and dedicate our present oral cavity to experimental purposes for the use of certain manufacturers of tooth paste.

In the meantime we will continue to employ our knowledge of chemistry, physiology, bacteriology, the needs of the patient, the results of our experience, and perchance some horse sense, in the conduct of our professional duties, rather than to base our actions on sales talks, or the tricks of an ad writer.—W. S. Kyes, in Bulletin of San Diego County Medical Society.

ANOTHER COMMITTEE ON THE NURSING PROBLEM REPORTS

The committee appointed and financed by the Rockefeller Foundation for the study of Nursing Education has made its report. The committee recommends:

The trained registered nurse for the care of the acutely ill, the present training course of three years to be enriched and improved and at the same time reduced to 20 per cent in length, without lowering standards;

The public health nurse, the supervising nurse, and the teacher in schools of nursing, who are to receive specialized postgraduate training in addition to the standard course for registered nurses;

The subsidiary nursing worker, to be trained by an eighteen months' course and licensed as nursing aide or nursing attendant for the care of minor and chronic illness and convalescence;

The Committee emphasizes the supreme value of combining bedside and instructive public health nursing and urges that the nurse who renders direct professional service in lessening the burden of illness has an overwhelming advantage then and thereafter in teaching the lessons of hygiene;

As to her training, it is the judgment of the Committee that the public health nurse, as a teacher of hygiene in the home, should be equipped with no less thorough training than that accorded to the bedside nurse, further supplemented by special studies along lines of public health and social service.

The most valuable feature of the report is the committee's condemnation by faint praise of the cheap circus buffoonery of one sort or another that is being exploited in many places by regularly organized propaganda methods to replace education and practice in a field requiring education and training:

The new educational objectives of the health administrator may be approached to a limited extent by mass methods. The printed page, the public lecture, the exhibit, the cinematograph, the radiogram, help to prepare the ground and make success easier. The ultimate victory over ignorance is, however, rarely attained in such ways. Direct personal contact with the conditions of the individual life is essential to success in a matter so truly personal as hygiene. . .

The majority of trained nurses are concentrated in the larger cities so that the rural districts in many states are wholly lacking in service of this kind. The evidence is that at present, in the cities, the supply of trained nurses is adequate for existing demands in normal times. The reason that so many persons who need nursing care in hospitals and in the homes of the poor fail to receive it, is to be sought in economic factors, rather than in a shortage of nurses.

On the question of nursing education requirements, the committee takes a positive stand in these words:

That for the care of persons suffering from serious and acute diseases the safety of the patient, and the responsibility of the medical and nursing professions, demand the maintenance of the standards of educational attainment now generally accepted by the best sentiment of both professions and embodied in the legislation of the more progressive states; and that any attempt to lower these standards would be fraught with real danger to the public.

The committee endorses the subsidiary, substandard or apprentice nurse:

That steps should be taken through state legislation for the definition and licensure of a subsidiary grade of nursing service, the subsidiary type of worker to serve under practicing physicians in the care of mild and chronic illness, and convalescence, and possibly to assist under the direction of the trained nurse in certain phases of hospital and visiting nursing.

The report states that their survey of the situation:

Does not indicate that the income of the private duty nurse is at present generally an exorbitant one, when we take into account the degree of unemployment—amounting in a typical group of 118 nurses to a week each month during the busy winter season. The solution of the economic problem which confronts the family of low income probably must be sought along the lines of cost distribution through some form of community organization, or along the lines of group insurance.

The report condemns the "apprentice" method of training by which most nurses have been educated. Their conclusions are based upon a study of:

twenty-three carefully selected schools, representing the main types of hospitals in various sections of the country and the best current practice in nursing education, were studied in detail. Defects were found in both the practical ward training and in the class room teaching. Inadequate laboratory equipment, excessive night work, inadequate supervision of student nurses, and lack of an intelligently planned progressive course of study are among the points mentioned for criticism. Most striking of all, however, according to the Committee's report, was the factor of time wasted in procedures essential to the conduct of the hospital, but of no educational value to the student concerned. Hours and days spent on the work of a ward maid, in putting away linen, in sterilizing apparatus, in mending rubber gloves, in running errands, long after any important technique involved had become second nature, accounted in one typical hospital where this problem was especially studied for a clear wastage of between one-fourth and one-fifth of the student's working day.

The remedy proposed by the committee is as follows:

It is fundamental to the success of nursing education that adequate funds should be available for the educational expenses of the school itself, and for the replacement of student nurses by graduate nurses and hospital help in the execution of routine duties of a non-educational character. With the necessary financial support, and under a separate board or training school committee, organized primarily for educational purposes, it is possible, with completion of a high school course or its equivalent as a prerequisite, to reduce the fundamental period of hospital training to twenty-eight months and at the same time, by eliminating unessential, non-educational routine, to organize the course along intensive and co-ordinated lines with such modifications as may be necessary for practical application; courses of this standard would be reasonably certain to attract students of high quality in increasing numbers. . .

The working day of the student should also be reduced to eight hours. More than eight hours on the average is now required in ward duty alone, exclusive of all class room instruction.

For the education of subsidiary nurses the report recommends:

That when the licensure of a subsidiary grade of nursing service is provided for, the establishment of training courses in preparation for such service is highly desirable; that such courses should be conducted in special hospitals, in small unaffiliated general hospitals where nurses are also trained; and that the course should be of eight or nine months duration, provided the standards of such schools be approved by the same educational board which governs nursing training schools.

Experienced persons always have realized that the real problem of nursing education was financial. The recommendations of the committee would increase the cost of educating nurses enormously. They realize this and recommend:

That the development and strengthening of university schools of nursing of high grade for the training of leaders is of fundamental importance in the furtherance of nursing education.

The training of nursing aides will cost money; the training of nurses will cost more money; the university school will require endowment. The hospital, in its operation of the training school, has for generations been trying to make bricks without straw. It is time that the hospital should be relieved from the dilemma of exploiting student nurses on the one hand, or of diverting funds given for the care of the sick on the other, by the provision of endowment specifically devoted to the purpose of education.

To Combat the "Ism"-ites—A Boston dispatch of August 19 reports the incorporation of a society, largely made up of members of the Massachusetts Bar, "to oppose further Federal encroachment upon the reserved rights of the States." Another announced purpose is "to stop the growth of socialism." This is cheering. The good Lord knows that the country needs some sort of organized effort to counteract the innumerable movements tending more and more in the direction of bureaucracy. The present year has witnessed a dangerous growth in number and variety of movements tending to radicalism, socialism, and the several other "isms," particularly at the Nation's capital.—Argonaut.

Counties Appropriate Funds for Full-time Health Departments—"Monterey, San Luis Obispo, and Riverside Counties have each appropriated $5000 for the establishment of full-time health departments in their respective counties. San Joaquin County has about completed plans for the establishment of such a department."—Weekly Bulletin, California State Board of Health.

"OBESITY CURES"

Never before in the history of advertising has there been so much money expended in advertising so-called "Obesity Cures." They are of every class and description. It is particularly fortunate that the Propaganda Department of the American Medical Association has seen fit to issue a new pamphlet on this subject. Every physician ought to have this pamphlet and read it. In the introduction, we read: "Women's fashions during the past few years gave a wonderful stimulus to one branch of quackery—the exploiters of 'obesity cures.' The desire to be slender — and slender to a degree often far beyond that compatible with good health—caused thousands of women to throw away money on so-called reduction treatments that were either dangerous or worthless, and sometimes both. Thyroid extract was the basis of many of the 'fat reducers' first put on the market, and this drug is still used in some of them. The public, however, has been warned of the dangers of this powerful agent, so that it is becoming increasingly difficult for those who live on the fat of the land to sell remedies of this type. . . .

"Practically every 'fat cure,' no matter to what type it belongs, is exploited under two specific claims: First, that those who use it do not need to diet; second, that they need not exercise. It is hardly too broad a statement to say that every 'obesity cure' is also sold under the claim that it is different from every other 'obestity cure.' The most wildly extravagant representations are made by the dispensers of these worthless cures. Especially is this the case in those that are sold on the mail-order plan rather than directly through the drug stores. It is after the purchaser has parted with her money that she finds how widely the 'treatment' she has purchased differs from what she had been led to believe it was. The preparations discussed in this pamphlet are but a few of the hundreds on the market. They are, however, typical."

The pamphlet, of course, is limited to the most widely advertised of these alleged cures, and the list includes interesting information regarding alleged cures that are advertised extensively, including California. The "cures" exposed are: "Absorbit Reducing Paste," "Allan's Anti-Fat," "Antipon," "Arbolone Tablets," "Auto-Masseur," "Z. T. Baker," "C. H. Barbour," "Basy Bread," "Berledets," "Biel (Hattie) & Co.," "C. E. Biel," "M. S. Borden Co.," "Botanic Medicine Co.," "H. C. Bradford," "F. T. Brough," "Burns Belt Co.," "G. F. Cain," "Clark's Thinning Salts," "Corpulin," "W. C. Cunningham," "Dalloff's Tea 'Contre l'Obesite,'" "Doctors' Essential Foods Co.," "Jean Downs," "Elimiton (Hurwitt)," "Every Woman's Flesh Reducer," "Fatoff," "Fell Reducing Treatment," "Figuroids," "Get Slim," "Graziana Reducing Treatment (Zehrkur)," "Texas Guinan, Inc.," "Marjorie Hamilton," "Hargreave's Reducing Wafers," "Hughes & Hughes XL Reducing Pills," "G. J. Hurwitt," "Interstate Drug Co.," "J. Z. Obesity Tablets," "F. J. Kellogg," Kellogg's Safe Fat Reducer," "Lucile Kimball," "J. A. Knox," "Oil of Korein," "W. Lawlor," "Louisenbad Reduction Salt," "Marmola," "Modern Vacuum Cap Co.," 'Morlene," "Nelson Lloyd Treatment," "Newman Obesity Cure," "Nikola," "Normal Pills," "Onadal," "Parnotis," "A. J., J. N. and N. Petrucci," "Phatolene Tablets," "Phy-thy-rin," "Phytoline," "Protone Co.," "Rengo Co.," "Russell's Anti-Corpulent Preparation," "Sanitone Wafers," "Sel Amaigrissant Clark," "Seymour Treatment," "Society of Associated Physicians," "R. T. Stradus," "Sylphine," "Trilene Tablets," "(F.) Turner Triplex System," "Verlie Gatlin Co.," "Vincent's Anti-Stout Pills," "Walker Pharmacal Co.," "A. Gordon Wallace's, Treatment," "M. Wood," "Pale's Fertilizer Tablets," "Zobeide."

All of these propositions are analyzed and commented upon freely in the pamphlet referred to. For example, one of these products most extensively advertised in California is "Marmola." This product has been analyzed and was shown to contain essentially the following:

Dried thyroid gland	1.4 gr.
Phenolphthalein	0.4 gr.
Sodium chlorid	0.7 gr.
Powdered Fucus vesiculosus (bladderwrack)	5.0 gr.
Extractive	2.5 gr.
Oil of peppermint	trace

Any product which depends for its essential action on the presence of thyroid extract is much too dangerous for indiscriminate use. Physicians have, at various times, reported cases of patients with severe or obscure nervous symptoms that investigation showed were due to the taking of some "patent medicine" containing thyroid extract.

Validity of License Tax on Physicians—We are frequently asked as to the legality of county, municipal and other local taxes on physicians. The following case of the city of Redding v. Dozier (California), 206 Pac. R., 465, will answer the question permanently:

"The District Court of Appeal of California, Third District, in affirming a judgment in favor of the plaintiff city for $10, which was alleged to be due as a license tax imposed under an ordinance adopted by the city, says that the defendant was a physician and surgeon residing and practicing in the city and having his office at his place of residence. The city is one of the sixth class. The ordinance was entitled 'An ordinance to license various classes of business, shows, exhibitions and games within the city of Redding for the purpose of revenue and regulation, and fixing the rates of license tax upon the same and providing for the collection of the same by suit or otherwise.' Section 1 provided that every person, firm, etc., who had a fixed place of business, and engaged in, carried on, or conducted any business, exhibitions or games described in this ordinance, within the city, should pay a license therefor in the amount thereinafter specified. Section 2 provided that the licenses to be paid, the persons who should be required to pay the same and the business on which the same were to be paid were, besides others, '(29) lawyers, doctors and dentists, $5 per quarter.' The principal question raised was whether the city had authority to impose the tax. The court thinks that it had, under the statutes of the State. In Ex parte Johnson (Calif. App.), 190 Pac. 852, it was held that a city may impose a license tax for carrying on the business of a lawyer at a fixed place of business. In Ex parte Falusha, 194 Calif. 697, 195 Pac. 406, the Supreme Court of California reached the same conclusion. It must be held that the same rule applies to a physician and surgeon.

"The complaint in the present case alleged that the 'defendant was and now is a doctor practicing medicine and having his office and principal place of business in the city of Redding.' The defendant argued that the allegation as to place of business was not the equivalent of a 'fixed place of business.' The court deems the criticism hypercritical. The defendant testified that he had a large practice; that he received patients at his residence and performed operations there; that he regularly kept patients at his residence for treatment when they required close observation; that there was no room in his residence designated as an office, but that he treated his patients in the living room; and that he treated most of his patients at their homes. The foregoing evidence, coming from the defendant, the court thinks showed conclusively that he had a fixed place of business and that the alleged defect in the complaint, if conceded to be a defect, could not have prejudiced his rights.

"Hearing was denied by the Supreme Court of California."

QUACKERY, MIRACLE HEALING AND MEDICAL CULTS

(By Robert W. Lovett, Boston Medical and Surgical Journal.)

If one goes backward in the history of civilization, one finds wherever and whenever one looks into it, three persistent parasites clinging to each successive stage of civilization. These are drunkenness, prostitution, and quackery. The State legislates against them; the Church fulminates against them; the better part of the community from time to time rises and decides to exterminate them; but in the Vedas of India, the classics of Greece and Rome, the early records of Egypt and Arabia, and the writings of the Middle Ages, you will find that parasite with which we are for the moment concerned—quackery—described, deplored, and condemned in terms almost of today.

To maintain such vigor, such persistence and such superiority over all the efforts of Church, State, and Society to overcome it, quackery must have deep roots in human nature, and it is of interest to inquire what these roots are.

Causes of Quackery—The first of these lies in human gullibility. It has never been better expressed than by Butler in the following lines from Hudibras:

> The world is generally averse
> To all the truths it sees and hears;
> But swallows nonsense, and a lie,
> With greediness and gluttony.

The part of the people that can be fooled all the time includes several groups, each of which is fertile soil for the quack: (1) the very ignorant; (2) a peculiar class which seeks the mystical, the occult, and the irregular; (3) an unreasonable class, which espouses an unpopular cause, simply because it is unpopular, without any investigation of its merits, and which finds in the occult mysticism of India a satisfaction which does not come from the contemplation of facts as they are. One might describe them as a submerged class—submerged in the matter of reason and common sense.

The proportion of the gullible class in any community varies, but the estimate of a celebrated quack may be of interest. He was visited by a former play-fellow from his native village, who asked how he had got on so well, adding with the frankness of early friendship, "Thee knowst thee never had no more brains than a pumpkin." The quack took him to the window and bade him count the passersby. When a hundred had passed, the quack asked his visitor: "How many wise men do you suppose were amongst this hundred?" "Mayhap one," was the reply. "Well," returned the quack, "all the rest are mine."

In the history of the past there is no more amusing group of rogues than the famous quacks of the ages. Facile, specious, without conscience, and with unlimited daring, they come down through the years, not depressed by adversity, and always ready to trade on human gullibility."

Types of Quackery—Taking quackery and irregular practice from the time of Hippocrates (460 B. C.), the Vedas of India (600 B. C.), or the time of Galen, the stream flows down through the centuries in five main channels, and in analyzing these it will be interesting to see how little is new in modern cults. These channels are as follows:

1. Nostrums and Proprietary Medicines.
2. Miracle Healing.
3. Mental Healing.
4. Methods of Manipulation.
5. The Amateur Quack.

(1) **Nostrums and Proprietary Medicine**—These are sold in part with criminal intent and in part, probably, by stupid people, who believe in the efficacy of their concoctions. There is, however, no question of the intentions of the man who sold a morphine cure, containing morphia, or an inert cancer cure, or a disguised cocktail to innocent persons who were appreciative of the subsequent comfortable feeling, now described as "the kick," but ignorant whence it came. The antiquity of this branch of quackery is doubted. So long as medicine consisted of charms, amulets, and incantations, not much could be done in the way of faking imitations; but when remedies became established, so did nostrums.

(2) **Miracle Healing** — The subject of miracle healing is of established antiquity, but whether one view it from the point of view of the past or of today, it is too closely allied with religion to be discussed without the danger of giving offense. It is to be divided into three main divisions: (a) miracles in response to prayer; (b) miracles claimed by Christian Science, such as the cure of cancer; and (3) miracles by the laying on of hands, with or without prayer. The first-named is perhaps best seen in the miracle churches of Lourdes and St. Anne de Beaupre.

(3) **Mental Healing**—In this matter, also, too free discussion is likely to bring one into contact with religious belief, and the subject can be dealt with only superficially. It may be divided into three main groups: Christian Science; The Emmanuel Movement; and Mesmerism. A cure by mental healing implies an action of mind on body, not necessarily a direct miracle with the reversal of Nature's laws, but a healing by the natural mechanism of the body. This is best exemplified in Christian Science, which also figured in the last section; and those interested will find ample literature at their disposal. The Emmanuel Movement was based on the assumption that medical men did not sufficiently use the spiritual and mental aspect of therapeutics in their treatment of the sick, and that this could be supplied from the outside, preferably by the Church. . . . There is plenty of literature concerning it for those interested. One quotation may be given. "Chronic ailments of every sort yield as if by magic to the benign influence of suggestion—headache, toothache, neuralgia, rheumatism, insomnia, epilepsy, hysteria, neurasthenia, alcoholism, morphine, tobacco, stammering, sciatica, St. Vitus' dance, nervous dyspepsia, constipation, goitre, tumors, paralysis, etc."

(4) **Methods of Manipulation** — Bone-setting, osteopathy, and chiropractic. All other forms of irregular healing have at the present time largely given place to those by methods of manipulation. Of the three manipulative sisters, bone-setting, osteopathy, and chiropractic,

Bone-setting — Reference to manipulative treatment akin to bone-setting is found as early as the days of Homer, and it is probable that its origin is even earlier than this, although actual record of it seems to be lacking. Among the other camp followers of medicine were the gymnasts or Iatraleiptes, who, besides exercises, practiced inunction of the body. They were also, it would appear, bone-setters, and were naturally led to give first aid in all accidents and in many diseases, and to advise as to diet and regimen.

Osteopathy on analysis seems to be bone-setting, not much modified, but to which has been added a fantastic and unproved pathology to account for the claimed efficiency of its methods. An interesting quotation may be taken from one of the standard osteopathic text-books: "There is no doubt in my mind as to the similarity existing between the conditions which were recognized by so-called 'bone-setters' and those which have formed the basis for the successful advance of osteopathy. The difference lies principally in the educational qualifications." After reading the osteopathic theory of disease one comes almost to admire old Mr. Hutton, who openly announced that he neither knew nor cared to know anything about anatomy.

It is, therefore, interesting to examine the tangible evidence as to this (osteopathic pathology)

which has so far been offered. Three varieties of proof are available:

1. In the dissecting room and at autopsy: The claim is made that dissections of bodies reveal anatomical lesions associated with disease of organs; these observations have been made at osteopathic colleges, but such changes have not been observed in the dissecting rooms of the medical schools of the world. The claim that these "lesions" are found is, therefore, apparently not substantiated by sufficient evidence, which is eagerly awaited.

2. The X-ray: It is claimed that the X-ray has frequently shown an osteopathic lesion, which disappeared after reduction. The experience of the medical profession is otherwise. It has only to be remembered how slight a distortion in the line of the shadow will produce the appearance of a displacement in an X-ray, and that the reading of an X-ray differs greatly. I can only state that in my personal experience in one or two instances I have been privileged to have taken in my own X-ray room, under fixed conditions, radiographs before and after the so-called "reduction" of a lesion by others. The closest analysis of the radiographs before and after failed to show the slightest change in the position.

3. Animal Experimentation: Bulletin V, of the A. T. Still Research Institute of Chicago, Ill., published in 1917, is a contribution to the study of the effects of experimental lumbar "lesions." "Lesions" were produced by forcible subluxation in which it is amusing to note that great care was taken to prevent any injury to the articular tissues. "Lesions" were also produced by gentle taps near the spinous processes of the selected vertebrae. These animals were then studied. So far as one can judge from the decidedly imperfect X-rays reproduced as evidence, a partial fracture of the spine was not uncommon. Various organs were then studied with regard to the effect of these lesions, but the work seems loose and very discursive, and is far from convincing. In this experimental work two especially long steps are taken by making assumptions which will demand better proof before animal experimentation can be of value. These assumptions are: (1) The frequency of osteopathic lesions of a demonstrable character existing in human beings; (2) that such lesions can be duplicated in quadrupeds by wrenching, tapping and manipulating their spines.

Chiropractic—When we come to the third and youngest, and least reputable of the three manipulative sisters, Chiropractic, we take a definite step downward. The Journal of Osteopathy speaks of chiropractors as "fakers," but the Supreme Court of Montana handed down a decision that "chiropractic is nothing more nor less than osteopathy under another name." The basis of the so-called "science" is the so-called "chiropractic subluxation" of a vertebra. This means a slight or partial separation between the articulations so that they are not exactly together. When a subluxation occurs there begins a pressure on the nerve coming through the intervertebral foramina and this shuts off the flow of life force going through that nerve and acts as a rheostat or booster to the current going through it. Chiropractically speaking, disease is simply a register as to the amount or excess of current that an organ receives at the end of the nerve: Slight pressure "steps up" the current; heavy pressure paralyzes. One would, therefore, adjust for cancer or gonorrhoea. This theory of disease is too fantastic, crude and unsupported to warrant discussion, but it spells danger to the community, and to what lengths it will go can only be appreciated by reading the testimony of B. J. Palmer in the Wisconsin courts. Chiropractors claim that they are licensed to practice in twenty-two States. The Universal Chiropractors' Association guarantees the graduate "the legal right to practice; or we will, through process of the law, know the reason why. . . . The fact that chiropractors are practicing in every State of the Union, and that the U. C. A. has not failed to protect them speaks for itself." In Massachusetts they have no standing whatever. The escape for the chiropractic in this State is to register as a masseur, but to pose as a chiropractor. If he is caught, he has only to claim that he is practicing massage. It seems not unlikely that a definite attempt will be made in this State to establish a licensing board for chiropractic.

(5) **The Amateur Quack**—The last and fifth division of the irregular practitioner has not been, up to this time, sufficiently appreciated. The amateur quacks outnumber all the others put together. They are active in every community. They are actuated by altruistic motives and they do only a moderate amount of harm. The prevalence of these amateurs in medical matters is not new.

If any one of you will do your knee up in a ham splint and bandage, and take a pair of crutches and go three or four miles in the trolley cars, you will find out two things: The desire of everybody to be considerate and to make room for the invalid to sit down, and the curiosity, unconcealed, but outspoken, of many of your fellow-passengers as to the cause, history, and progress of the ailment. People who have never heard of Mr. Howells' well-known man, in Chicago, who made his fortune by minding his own business, are eager to offer advice. You may give them whatever diagnosis you like, varying from a sprained knee to sarcome, or fractured patella, and you will find that they have either had it themselves, or had a relative or friend who had it, and the treatment by which he was cured was something entirely different from yours, unless the result was fatal, in which case you will be informed of that. The number of remedies proposed is legion, and it is surprising to find that more people are not unsettled by this sort of thing.

Percentage of Hospitals Admitting Osteopaths—Question 1 of the Round-Table Session of the American Hospital Association's annual meeting was, "What percentage of the hospitals in the association allow osteopaths to care for patients in the hospital; and under what conditions, if any, are they allowed?"

The answer, given by Dr. W. P. Morrill, Shreveport (Ala.) Hospital: "By the questionnaire method the following figures were obtained in relation to the percentage of hospitals which allow osteopaths to care for their patients: 83 1/3 per cent do not admit them; 11 1/3 per cent admit them under the supervision of M. D.'s; 3 per cent permit them to practice independently." Some extremely amusing and illuminating comments accompanying the questionnaire replies were read by Dr. Morrill. One institution admits osteopaths if the patient will sign a paper assuming full responsibility; another admits but "does not encourage" them; one writes, "They shall not pass."—The Modern Hospital.

Women's Foundation for Health, Inc.—A large, enthusiastic, and apparently earnest body of women and women's organizations of the United States have been brought together under the above title. According to the literature: "The Women's Foundation of Health, Inc., is a co-operative body of leading women's organizations formed with the purpose of correlating the health activities of the various organizations in a program emphasizing the positive phase of health." The objectives as published are: "To establish the conviction that health is generally attainable through individual effort and responsibility," and "To establish the conviction that mental health is as procurable as physical health." The present board of nine trustees contains the names of two physicians—Dr. Anna L. Brown and Dr. Martha Tracy. Headquarters of the foundation are at 43 East Twenty-second Street, New York City.

STATE SOCIETY

MEMBERSHIP OF THE STATE MEDICAL SOCIETY

The following tabulation shows by Counties the actual membership in the State Medical Society and in the Indemnity Defense Fund for the years 1921 and 1922:

	1921		1922	
County	Members	I. D. F.	Members	I. D. F.
Alameda	291	112	309	128
Alpine	19	9	17	9

	3405	1150	3605	1333

There are about 3000 educated physicians licensed to practice in this State who are not, but should be members of the State Medical Society.

THE 1923 MEETING OF THE AMERICAN MEDICAL ASSOCIATION, SAN FRANCISCO, TUESDAY TO FRIDAY, JUNE 25 to 29

The California Medical Association, with all of its constituent members; the League for the Conservation of Public Health; and the San Francisco Convention and Tourist League, with all of its affiliated organizations, are combining to make the 1923 Meeting of the American Medical Association a memorable one.

Permanent headquarters for all of the committees and for all matters pertaining to the 1923 meeting have been established at 806 Balboa Building, San Francisco. Any person or organization desiring any information on any point within the jurisdiction of the local committee of arrangements, or any assistance or other service connected with the annual meeting, are requested to address their communications to these offices. It will not be nesessary to remember the name of any committee or committee officer, because all mail, both incoming and outgoing, connected in any way with the California end of this work, will be distributed through our headquarters offices.

In addition to all matters medical, inquiries regarding transportation, sightseeing, California resorts, hotels, shopping, or any other matters of business or pleasure, will be promptly referred from these central offices to people competent to handle the situation.

Through the co-operation of the San Francisco Convention and Tourist League; the San Francisco Chamber of Commerce; the Northern Californians, Inc., and other social, commercial and industrial organizations, it is hoped that every service and every convenience possible will be made available to every person coming to California under the auspices of the American Medical Association. San Francisco already is a great national convention city. One hundred and fifty-eight national conventions will have convened in that city during 1922 and a larger number are scheduled for 1923.

There are ample splendid hotel facilities for all who wish to come. Details of the scheduled prices of 30 or 40 of these hotels will be furnished shortly by our committee on hotels, working with the Northern California Hotel Men's Association. Reservations may be made at any time by addressing the headquarters offices, San Francisco, or the hotel of your choice.

Reservations have been made at the Palace Hotel for the trustees and other officers and delegates of the American Medical Association.

All of the work of the convention will be held in one building, the Civic Auditorium, which has more rooms of ample size than will be needed, with plenty of committee rooms and offices for all officers and sections, in addition to ample space for both scientific and commercial exhibits. This building is within the zone of the great business, shopping and hotel center of the city.

Committee of Arrangements

(An ex-officio committee representing the various medical organizations of California)

Executive committee: W. E. Musgrave, chairman; Ina M. Richter, secretary; John Gallwey, treasurer.

Ray Lyman Wilbur, President-Elect American Medical Association; Henry G. Brainerd, President State Medical Society; T. C. Edwards, President-Elect State Medical Society; W. W. Cross, Second Vice-President State Medical Society; William Ophuls, Dean of Stanford Medical School; L. S. Schmitt, Acting Dean University of California Medical School; Percy T. Magan, Dean of College of Medical Evangelists; George E. Ebright, President State Board of Health; Dudley Smith, President League for the Conservation of Public Health; Robert Pollock, President Southern California Medical Association; J. R. Snyder, President Northern California Medical Association; Saxton T. Pope, President San Francisco County Medical Society; Donald J. Frick, President Los Angeles County Medical Society; E. E. Brinckerhoff, President Alameda County Medical Society; W. W. Crawford, President San Diego County Medical Society; G. P. Dillon, President Sacramento County Medical Society; L. R. Johnson, President San Joaquin County Medical Society; Raymond Wayland, President Santa Clara County Medical Society; G. W. Walker, President Fresno County Medical Society; James H. Parkinson, representing all other Northern County Society Presidents; George H. Kress, representing all other Southern County Society Presidents; Howard H. Johnson, Associate Secretary of the California Medical Association; the chairmen of all subcommittees, as follows:

Dr. A. W. Hewlett, chairman subcommittee on

sections and section work; Mariana Bertola, chairman subcommittee on registration; Rene Bine, chairman subcommittee on commercial exhibits; Frank Hinman, chairman subcommittee on scientific exhibit; Harry E. Alderson, chairman subcommittee on entertainments; Morton R. Gibbons, chairman subcommittee on hotels; Alfred C. Reed, chairman subcommittee on printing; R. Knight Smith, chairman subcommittee on finance; John H. Graves, chairman subcommittee on publicity.

Names of chairmen of sub-subcommittees and other members of committees will be published next month.

Fears Excess in Standardization—Dr. George D. Stewart, president of the New York Academy of Medicine, in an entertaining address opened the general session (American Hospital Association) on Tuesday evening. His subject was "Standardization Values" and he sounded early warning that he did not set too high an estimate on that practice, which has lately become the cry of the hour.

"Nowadays," began Dr. Stewart, "we standardize everything from shipbuilding and hospital administration to birth control and control of appetites. Standardization is largely begotten of our economic necessities and sometimes it leaves out all other considerations. It is a recognition of the fact that we have exploited our natural resources and if carried to excess hinders progress.

"The standardization of medicine and of hospital management may result in much good or in great danger. The easiest way to settle down into a rut is to standardize. I have even heard of one hospital superintendent who issued typewritten directions for its staff members to follow in performing an operation. I deplore the attempt to make me do a thing a given way, if I can do it a better way.

"Standardized histories in the hospital can constitute a source of great error, if made by one man and filled in by another. In my opinion, the histories should be made by the man himself and interpreted by him. Collectivism and standardization lead toward communism, and in communism individuality is relinquished entirely."—The Modern Hospital, October, 1922.

A County Contract With the County Medical Society—"The Board of Supervisors and the Cherokee County Medical Society, according to a statement in the Herald, a paper published at Stuart, Iowa, have entered into a contract whereby the medical society agrees to attend to all medical and surgical needs of the poor in the county until January, 1923. The county is to pay the medical society the sum of $3500, which, at the termination of the contract, is to be distributed among the members of the society in proportion to the amount of work done by each. Under this arrangement a dependent person is to have the privilege of selecting his attending physician from among the membership of the society, which, we are told by the Herald, includes practically all the doctors in Cherokee County.

"This is a somewhat novel contract and it will be interesting to see how the arrangement made will work out. In most counties the governing authorities enter into a contract with one physician, some with a stated compensation, some on a fee basis, who serves all indigents receiving medical and surgical care at the expense of the county. The Cherokee County plan will remove the occasion for a complaint, frequently made by indigents, to the effect that the service rendered by the "county doctor" is not satisfactory, because under this plan the dependent person will choose his own medical attendant."—Bulletin A. M. A., Oct. 1922.

COUNTY NEWS

CONTRA COSTA COUNTY

Contra Costa County Medical Society (reported by L. St. John Hely, secretary)—The society met in regular monthly session at the home of C. R. Leech at Walnut Creek, October 28, 1922, with the following members present: Clara and J. B. Spalding, Auslen, Gregory, Neff, Beard, Cunningham, Carpenter, Marks, Kelly, Smith, Leech and Hely. Mrs. Auslen and Mrs. Leech were guests. Ethan H. Smith of San Francisco read a paper on fractures, discussing the subject from all angles and presenting methods of treating broken bones of different parts of the body. Kelly of the State Hygienic Laboratory of the University of California demonstrated and gave an interesting talk on the Schick test. The epidemic of diphtheria at Pinole was completely stamped out by this method. This was also done at Tracy, where there was another epidemic.

After the meeting, a luncheon was served by Mrs. Leech. The annual meeting in November will be held at the Hotel Oakland at dinner, followed by a theatre party at the Orpheum.

FRESNO COUNTY

Fresno County Medical Society (reported by Thos. F. Madden, secretary)—The Society met November 7, at the Commercial Club, Fresno, with the following members present: Aller, Breemser, Brown, Collins, Couey, Cross, Divanovich, Goldberg, Jamgotchian, Jorgenson, Kjaerbye, Long, Madden, Manson, Montgomery, Milholland, Schiro, Schottstaedt, Sciaroni, Sheldon, Stein, Tillman, Trowbridge, J. R. Walker, G. W. Walker, Weise, Willson, Dearborn and O'Neill.

Applications for membership were received from E. R. Scarboro and A. A. Calaway.

F. W. Lynch of San Francisco presented a paper entitled "Certain Fundamental Features Concerning Retroversion of the Uterus." This paper was discussed by C. D. Collins. C. P. H. Kjaerbye presented a paper entitled "Psychoneurosis, Its Relation to the General Practitioner."

Arrangements have been made for members of this society to meet with members of the Merritt Hospital staff in Oakland on the evening of December 2nd. A scientific program will be prescnted, also entertainment. Chester Rowell will give a short address.

LOS ANGELES COUNTY

County Hospital—Norman R. Martin, Superintendent of Charities of Los Angeles County, in making a merited appeal for a bond issue, gives some interesting statistics about the work of the Department of Charities, including the County Hospital:

"The average daily patient population for the fiscal year ending June 30, 1921, was 1038; for the year ending June 30, 1922, similar average was 1133, or a total daily increase of 94 patients. The daily average of employees during the last fiscal year was 688; and the average number of patients to each employee, 1.65.

"There are 45,000 persons handled yearly through the Hospital receiving room, but only 15,000 of these are admitted as bed patients. A large proportion of the remaining 30,000 could be treated with a fair degree of satisfaction through an outpatient department. This figure emphasizes the importance of establishing at once such a department of competent organization and capacity."

Olive View Sanitarium—This sanitarium for patients suffering from tuberculosis is owned and

operated by the city and county of Los Angeles. It is often improperly termed the Sylmar Sanatorium. This institution is located in the foothills, twenty-five miles from Los Angeles by paved highway, and four miles north of San Fernando at an elevation of 1500 feet and overlooking the beautiful San Fernando Valley. It comprises 454 acres of land, ideally situated, and was opened on October 27, 1920. Patients are admitted through the Los Angeles County Hospital. Present construction consists of one Infirmary Building, 357 feet long, including 26 private rooms and suitable accommodations for administrative offices as well as facilities for surgery, X-ray and dentistry, pan rooms, blanket warmers, linen rooms, diet kitchens, etc.; ward buildings with community sitting room, twelve ward beds on either end, with two private rooms and nurses' chart room, as well as ample lockers, bath and toilet facilities; Service Building containing main kitchen, bakery, dining rooms for male and female patients and for different types of employees, refrigerators and storeroom; two two-story cottages for employees, modern and up to date in every particular; and one Superintendent's cottage. Water supply—Los Angeles aqueduct crosses the property and a buster pump forces water to a 300,000 gallon reservoir 175 feet above the property. There is also a reserve water supply from a well. Sewer system—Septic tank. Construction is now being commenced for eight additional ward buildings, three for ambulant cases and five for hospital type cases. When completed, the two present ward buildings will probably be used for the hospital type cases. Within a short time construction will be commenced of two additional two-story employee cottages; a complete power plant; laundry; and utility building, housing linen room, mechanics' shops, pump house, etc. The completion of these new improvements within the next nine months will give this institution a capacity of 300 beds. At that time it is expected to still further increase the capacity by 200 additional beds, making a 500 bed institution. It is the expectation to transfer, as soon as possible, all of the tuberculosis patients from the County Hospital to Olive View Sanatorium with the idea of retaining only at the County Hospital "clearing house wards," male and female, admitting all patients to Olive View through the Hospital. This will be more convenient for patients and will retain to the medical profession the observation and preliminary treatment of such cases at a convenient point. Transportation between the Sanatorium and San Fernando and Los Angeles is covered by one truck, one Cadillac bus, one 7-passenger Hudson touring car and one Ford. The Sanatorium is a portion of the Department of Charities, and is operated as a ward of the County Hospital division.

MADERA COUNTY

Bond Issue for Madera County Hospital Defeated—Madera County voters defeated a proposed $150,000 bond issue in the election Tuesday, November 7.

MONTEREY COUNTY

Salinas Valley Hospital Open—The Old Red Cross health center of Salinas has been purchased by a co-operation and converted into an eight-bed hospital. This hospital is now in operation and open to all doctors of medicine of the community.

ORANGE COUNTY

Full-Time Health Department for Orange County—"The supervisors of Orange County last week appropriated ten thousand dollars for the establishment of a full-time health department in that county. Dr. A. H. Domann, county health officer, was largely instrumental in bringing about this result. His enthusiasm, vision and public-spirited attitude mean much for the future of public health in Orange County. The various municipalities of the county will, undoubtedly, co-operate and join the full-time department. It is planned to establish a bacteriological laboratory in co-operation with the county hospital.

"Monterey and San Luis Obispo counties have already appropriated money for the establishment of full-time county health departments, and it is believed that at least two other counties will soon perfect plans for the establishment of similar organizations." (Weekly Bulletin, California State Board of Health, October 21, 1922).

RIVERSIDE COUNTY

Mary Henderson Sanatorium—The Seymour Sanitorium at Banning has been sold to Miss Mary Henderson and the name has been changed to the Mary Henderson Sanatorium, with two classes of service—one for general hospital patients and the other for convalescents.

SAN BERNARDINO COUNTY

San Bernardino County Medical Society (reported by E. J. Eytinge, secretary)—The society met November 3 at the San Bernardino County Hospital, with 25 members present and 50 absent. There were also 25 guests. The address of the evening was given by H. A. Johnston of the Johnston-Wickett Clinic, Anaheim, on "Group Practice." C. G. Hilliard opened the discussion, which was general. The following officers were elected for the ensuing year: F. H. Folkins, president; G. S. Landon, first vice-president; E. L. Tisinger, second vice-president; E. J. Eytinge, secretary-treasurer. E. J. Eytinge was also elected delegate to the State Society and L. M. Coy was elected alternate. Will J. Reed was elected to membership, and J. A. Connell was admitted to membership by transfer from Los Angeles.

SAN DIEGO COUNTY

San Diego County Medical Society (reported by Robert Pollock)—About twenty-five members of the San Diego County Medical Society attended the Southern California Medical Society meeting in Los Angeles, November 3 and 4. The practice adopted by this society of holding its meetings at the week end induces many men to attend who otherwise would not. This plan could be followed with advantage by contiguous County Societies in mutual exchange of discussion. An occasional joint meeting of two or more neighboring County Societies furnishes splendid opportunity for generating sociability, as well as a live interest in scientific programs.

At the regular meeting October 24, three papers were presented:

1. Treatment of Drug Addicts by Thatcher Miller, M. D.
2. Chaulmoogra Oil in the Treatment of Tuberculous Laryngitis; Chas. W. Brown, M. D.
3. An Analysis of the Electric Vibration Claims of Albert Abrams; A. E. Banks, M. D.

This last was a serious attempt to apply the scrutiny of modern electric science to the claims in question, and was listened to with extreme interest to a late hour in the evening.

The program of the regular meeting of November 14 carried two papers:

1. Discussion of Some of the Principles Underlying the Treatment of Heart Disease, by J. F. Churchill, M. D.
2. Physiotherapy, by A. D. Butterfield, M. D.

On November 18 the San Diego Society and the Imperial Valley County Societies plan to hold a joint meeting at El Centro with a Symposium on the Respiratory Tract.

SAN FRANCISCO COUNTY

Stanford's Special Diet Laboratory—Stanford University Medical School and Hospitals has estab-

lished a unique dietetic laboratory for ambulatory patients and other persons. This diet kitchen is open to the public and diets are furnished upon prescription of physicians. Certain special foods for treating diseases are sold over the counter and also formulas for infant food are scientifically prepared and dispensed. This diet kitchen makes a specialty of diabetic, nephritic and reducing diets.

SAN JOAQUIN COUNTY

San Joaquin County Medical Society (reported by Dewey R. Powell, secretary)—The regular monthly meeting of the San Joaquin County Medical Society was held at the Receiving Department, State Hospital on Friday evening, October 13. Those present were: Hudson Smythe, J. E. Nelson, H. S. Chapman, A. C. Boehmer, H. J. Bolinger, W. P. Lynch, L. Dozier, N. B. Gould, W. J. Barnes, I. B. Thompson, H. E. Sanderson, R. T. McGurk, Grace McCoskey, Minerva Goodman, E. L. Blackman, J. T. Davison, C. F. English, H. C. Price, W. E. Weirich, Geo. Cooper, F. J. Conzelman, A. H. McLeish, F. S. Marnell, C. R. Harry, F. J. Blinn, J. D. Dameron, W. Friedberger and D. R. Powell, with Frank Lynch and Leo Eloesser of San Francisco as guests and speakers of the evening. The first speaker of the evening was Frank W. Lynch of San Francisco who spoke on "Retroversion of the Uterus." Lynch cited his statistical study of 1230 women who had been followed from 4 to 12 months after delivery. He found that retroversion occurred in 44 per cent of his clinic patients and in 19 per cent of his private patients showing that hard work following delivery had some causative part in the development and frequency of retroversion. It did not seem to be due to vaginal relaxation or to forceps delivery and was not influenced by the number of pregnancies. 76 per cent of the retroflexions occurred the first four months after delivery and 25 per cent had no symptoms. The treatment recommended for the first five weeks was the Kangaroo walk and later the pessary treatment. 72 per cent were cured by pessary treatment and 68 per cent had the symptoms entirely relieved. There were 189 cases operated on with 3.3 per cent recurrences. The speaker emphasized the necessity in operative technique of having two points of support. The value of early corrections following labor was clearly evident and 15 per cent of his patients had subsequent pregnancies. Numerous questions were asked by members and answered by Lynch. Leo Eloesser spoke on "Diseases of the Peripheral Blood Vessels." He spoke first of hemorrhage due either to injury or disease. He discussed the value of elevating the limb to control venous bleeding and the compression of an artery by the finger rather than the tourniquet, which may be left on too long and cause subsequent gangrene. He advised against packing the wound and against suture, stating that the vessel should either be tied off or let alone. He stated that in severe cases of oozing of the vessels, transfusion was the only real aid and stated that chemical coagulants were useless. He spoke of the value of using raw fresh meat in cases of bleeding from the gums. In the treatment of aneurysm wait until after collateral circulation is established before operation. Syphilis either causes thin walls with resulting aneurysm or causes thickened walls with resulting obliterative endarteritis. The treatment was rest in bed, elevation of the legs to relieve congestion and the use of Beers bandages to cause hyperemia. Heat was not efficient. The incision of the tendon sheath was often a prophylactic measure in gangrene, avoiding amputation wherever possible. Eloesser showed several interesting specimens and a number of X-ray plates illustrating the points he had made in his talk. He answered numerous questions which were asked him during the discussion.

SAN MATEO COUNTY

San Mateo County Medical Society met with the Santa Clara County Medical Society at Palo Alto November 15.

California Sanatorium Announces Reduction in Rates—Beginning October 1, the officers of this institution announce that the pavilion rate will be reduced from $40 to $35 a week. This rate includes everything necessary for the treatment of the patient.

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by A. C. Soper, secretary)—The October meeting was held at the Cottage Hospital on the 23rd of the month, with President Mellinger in the chair. There were twenty-two members and four visitors. Samuel Robinson presented the subject of "Tubercular Abscess of the Chest Wall." Ullmann, Cunnane, Culler and Freidell joined in the discussion. R. Manning Clarke read a paper on "Thirty-two Cases of Peptic Ulcer." This paper was discussed by Freidell, Stevens, Flint, Means, Bogan, Cunnane, Nagleman, Ullmann, Brush and Sansum. Robert M. Culler was elected to membership.

Celite Products Company Hospital—The Celite Products Company Hospital, which was completely destroyed by fire last May, is being rebuilt.

SANTA CLARA COUNTY

Santa Clara County Medical Society (reported by E. P. Cook, secretary)—The Monterey, Santa Cruz, San Benito and Santa Clara Societies met together at dinner in Gilroy on the evening of October 18. Short, informal talks were given by several members of the different societies. E. C. Fleischner of San Francisco presented a paper on the subject of diphtheria. That the paper was thoroughly enjoyed was evidenced by the many questions which it aroused in the subsequent discussion. John Clark of Gilroy was the able toastmaster, and the physicians of Gilroy again proved themselves perfect hosts.

The Santa Clara and San Mateo County Medical Societies held a joint meeting at the United States Veterans Hospital, Palo Alto, on the evening of November 15. The business meeting was dispensed with, and Colonel R. L. Stanley presented a scientific program of unusual interest. Case reports were read by Captain Fred Beardon and Major A. O. Saunders. Refreshments were served following the program.

SONOMA COUNTY

Sonoma County Medical Society (reported by N. Juell, secretary)—The society met at Cloverdale, October 19, with ten members and five visitors present and twenty-five members absent. A. Thurlow delivered a very interesting address on "The Problem of the Unstable," the mental attitude of hysteria and similar conditions and how to handle them. McLeod discussed the problems confronting the medical profession in the coming campaign and a committee was appointed in each town of the county to distribute literature and otherwise aid in defeating the three anti-health measures on the ballot.

During the banquet served by Dr. Shipley, a plan for the better health campaign in the county was discussed. Mrs. Hatch, a member of the Santa Rosa Board of Education, asked the opinion of the society of a plan proposed to have each of the seven high school districts appoint a visiting nurse under the county health officer. Dr. Pryor, the county health officer, suggested the addition of two or three field workers and Rogers suggested that Sonoma County would be a good place to work out some such plan.

The society met also on November 9, with seven members present and twenty-nine absent. There

were also twenty nurses present as guests. Alson R. Kilgore of San Francisco gave a talk on "Early Cancer."

Nurses' Home at Petaluma General Hospital Damaged by Fire—The Nurses' Home of the Petaluma General Hospital suffered a considerable damage by fire recently, the interior of the lower floor being completely destroyed. The origin of the fire was traced to an electric iron left in the kitchen with the current on, the nurses having gone to the hospital proper, two doors away, for luncheon.

STANISLAUS COUNTY

Stanislaus County Medical Society (reported by R. E. Maxwell, secretary)—The October meeting was held at Hotel Modesto, beginning with a dinner. The following members were present: Bemis, Delappe, McPheeters, Surryhne, Reamer, Finney, Field, Benson and Maxwell. E. H. Falconer of San Francisco addressed the society on the subject of "Recent Progress in the Study of Primary Anaemia," illustrated by lantern slides. A. R. Kilgore of San Francisco gave a short talk on "Cancer Propaganda," with suggestions as to its significance to the medical profession.

L. J. Peters was admitted to the society by transfer from the Alameda County Society. I. B. Thompson was given a transfer to the San Joaquin County Society.

Gift to St. Mary's Hospital, Modesto, by Knights of Columbus—Plans for the purchase of a modern X-ray apparatus to be presented to St. Mary's Hospital are being carried out by the Knights of Columbus of Modesto.

TUOLUMNE COUNTY

The New Hetch Hetchy Hospital—A new one-story eight-bed hospital building, 50 by 130 feet, has been erected to replace the one lost by fire two months ago. The hospital has been equipped and is now receiving patients.

YOLO COUNTY

Yolo County Medical Society (reported by Lela J. Beebe, secretary)—The regular quarterly meeting of the society was held October 3 at the County Court House, Woodland, with the following members present: Bates, Beebe, Blevins, C. H. Fairchild, F. R. Fairchild, Goffin, Lawson, Lawhead, Newton and Ward. The following members were absent. Bransford, Craig, Derosier, King, McManus, Parsons, Poage and Keith. Dr. Hayes of the Department of Veterinary Science of the University of California and Dr. H. H. Johnson, Associate Secretary of the State Medical Society, were guests of the society.

Johnson made clear the plans of the State Society in regard to the problems of industrial medicine, and also discussed the three anti-health measures on the November ballot.

Annual Meeting of Nevada State Medical Association—The annual meeting was held at Reno, October 6 and 7, 1922. All records for attendance were broken, there being sixty-four physicians registered, which was eighteen more than at any previous meeting. The following officers were elected: President, J. LaRue Robinson, Reno; first vice-president, A. Huffaker, Carson City; second vice-president, R. H. Richardson, Reno; secretary-treasurer, Horace J. Brown, Goldfield; trustee for three years, W. A. Shaw, Elko; delegate to A. M. A., Horace J. Brown, Goldfield; alternate, J. LaRue Robinson, Reno. The papers presented were excellent, and the discussions showed that the members are deeply interested in every phase of the practice of medicine—Abstracted from Nevada Medical Bulletin, October 15, 1922.

BOOK REVIEWS

Radium Therapy—By Frank Edward Simpson, A. B., M. D. 391 pages with 166 original engravings. St. Louis: C. V. Mosby Company, 1922. Price $7.00.

Simpson has written a very complete text on the treatment of disease with radium. The exposition of the theoretical phase of the subject is clear, comprehensive and well arranged. The discussion of dosage is somewhat too technical for some physicians, but properly belongs in this type of book. The presentation of the technic of treating specific clinical entities is based on the author's wide experience and can safely be used as a guide to the beginner in radium therapy. It is disappointing that no mention is made of the value, in many cases, of roentgen therapy in combination with radium therapy, particularly when the amount of radium available is relatively small. Any one interested in the subject will find this book worth reading, though its lasting value is limited by the changes which are constantly being made in the technic of radium theraphy in the light both of clinical experience and laboratory experiment. L. R. T.

Diseases of the Thyroid Gland—By Arthur E. Hertzler, M. D., Professor of Surgery in the University of Kansas School of Medicine; Surgeon to the Halsted Hospital, Halsted, Kansas; Surgeon to St. Luke's Hospital and St. Mary's Hospital, Kansas City, Mo., and to Provident Hospital, Kansas City, Kansas. With a chapter on Hospital Management of Goiter Patients, by Victor E. Chesky, A. B., M. D., Associate Surgeon to Halsted Hospital. 245 pages, 106 original illustrations, St. Louis; C. V. Mosby Company, 1922. Price $5.00.

This is not a monumental monograph. It was not so intended. It is an account of personal experiences told without pomp, and without pretense of profound erudition. And as such it is to be commended. Its thought and diction are surgical. That is to say, it reads quickly, and its style is decisive, clean cut, snappy, at times almost breezy. One may not always agree with the author's views or procedures, but at least one is not left in doubt as to their nature.

The book contains no bibliography and no attempt is made to review the literature exhaustively, but appropriate references are interspersed here and there.

Its contents are predominantly clinical and a worthy emphasis is accorded to a proper appreciation of symptomatology, diagnosis and treatment, and yet the reviewer regrets the scant consideration given to the important differentiation between toxic adenoma and toxic hyperplasia (Grave's Disease), which is so fundamental in judging the clinical course, estimating the prognosis and deciding upon proper therapy.

The physician will not enthuse over the hasty notes and almost flippant attitude toward basal metabolism estimation and X-ray or radium therapy. The title of the book is misleading, for it contains no chapters on childhood myxedema, adult myxedema or hypothyroidism. It would better have been entitled "Some Types of Goiter and their Surgical Treatment." The author deserves commendation for his conservative attitude toward prognosis. He has observed his patients over a great many years and thoroughly appreciates the life-long character of thyroid disease, the rarity of absolute cure, and the questionable value of most statistics. The publishers deserve hearty commendation for the

fine paper, clear large type, and excellent reproduction of Tom Jones' handsome illustrations. The latter are superbly done, and combine practical value with artistic beauty.

The thyroid surgeon of great experience does not need this book for reference, but it is worthy of careful perusal by the surgeons who from time to time have occasion to operate on the thyroid gland. It is written principally for them and it will be to their advantage to have it handy. H. L.

BOOKS RECEIVED

An Outline of the Medical Service of the Theatre of Operations. By M. A. W. Shockley, Lieutenant-Colonel Medical Corps, U. S. Army, Philadelphia: P. Blakiston's Son & Co.

An Outline of Pirquet's System of Nutrition. By Dr. Clemens Pirquet, Professor of Pediatrics at the University of Vienna, Austria. 16mo of 96 pages. Philadelphia and London: W. B. Saunders Company, 1922. Cloth, $2.00 net.

Lectures on Dietetics. By Max Einhorn, M. D., Emeritus Professor of Medicine at the New York Post Graduate Medical School and Hospital; Visiting Physician to the Lenox Hill Hospital, New York. 12mo of 244 pages. Philadelphia and London: W. B. Saunders Company. 1922. Cloth, $2.25 net.

The Treatment of Fractures: With notes upon a few common dislocations. By Charles L. Scudder, M. D., Assistant Professor of Surgery at the Harvard Medical School. Ninth Edition, Revised. Octavo volume of 749 pages, with 1252 illustrations. Philadelphia and London: W. B. Saunders Company. 1922. Polished Buckram, $8.50.

Animal Parasites and Human Diseases. By Asa C. Chandler, M. S., Ph. D., Instructor in Biology, Rice Institute, Houston, Texas. Second Edition, Revised. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Limited, 1922.

Our Medicine Men. By Paul H. DeKruif. 237 pages, illustrated, $1.75. New York: The Century Co. 1922.

Diseases of Women. By Harry Sturgeon Crossen, M. D., F. A. C. S., Clinical Professor of Gynecology, Washington University Medical School, and Gynecologist in Chief to the Barnes Hospital and the Washington University Dispensary; Gynecologist to St. Luke's Hospital; Consulting Gynecologist to the Jewish Hospital and the St. Louis Maternity Hospital; Fellow of the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons. Fifth Edition, Revised and Enlarged, with 934 illustrations. St. Louis: C. V. Mosby Company. 1922.

The Writing of Medical Papers. By Maud H. Mellish, Editor of The Mayo Clinic Publications. Philadelphia and London: W. B. Saunders Company. 1922.

Injury, Recovery and Death, in Relation to Conductivity and Permeability. By M. J. V. Osterhout, Professor of Botany. Philadelphia and London: J. B. Lippincott Company.

A Text-Book of Human Physiology. By Albert P. Brubaker, A. M., M. D., LL. D., Professor of Physiology and Medical Jurisprudence in the Jefferson Medical College; Formerly Professor of Physiology in the Pennsylvania College of Dental Surgery; Formerly Lecturer on Physiology and Hygiene in the Drexel Institute of Art, Science, and Industry. Seventh Edition, Revised and Enlarged, with 367 illustrations. Philadelphia: P. Blakiston's Son & Co.

Polaris, The Story of an Eskimo Dog. By Ernest Harold Baynes, illustrated. New York: The Macmillan Company. 1922.

Gonorrhea and Impotency. Modern Treatment. By Edwin W. Hirsch, S. B., M. D., American Electrotherapeutic Association, First Lieut., M. C., U. S. Army. With an additional lecture on Ultra-Violet Radiation by A. J. Pacini, M. D. Illustrated. The Solar Press, Chicago. 1922.

Public Relief of Sickness. By Gerald Morgan. New York: The Macmillan Company. 1922.

Principles and Practice of X-Ray Technic for Diagnosis. By John A. Metzger, M. D., Roentgenologist to the School for Graduates of Medicine, University of California, Southern Division, Los Angeles. With 61 illustrations. St. Louis: C. V. Mosby Company. 1922.

Dental and Oral Radiography. A textbook for Students and Practitioners of Dentistry, By James David McCoy, M. S., D. D. S., F. A. C. D., Professor of Orthodontia and Radiography, College of Dentistry, University of Southern California, Los Angeles. With 116 illustrations. Third Edition. St. Louis: C. V. Mosby Company. 1922.

The Southern California Medical Society (reported by Egerton Crispin, secretary, and Wm. Duffield, president)—The Southern California Medical Society held its sixty-seventh semi-annual meeting in Los Angeles on the 3rd and 4th of November. This was the most successful meeting the Society has had. The attendance at the Friday evening session numbered over eight hundred persons. Among the out of town speakers were Walter Alvarez of San Francisco, who presented a study on "High Blood Pressure" based upon "An Analysis of Sixteen Thousand Measurements on University Freshmen and High School Students." Andrew Thornton of San Diego presented a timely paper on "Immunization Against Diptheria," presenting arguments for its "universal application." Lyell Kinney, of San Diego, discussed the "Pathologic Gall Bladder" from a Roentgenological standpoint. E. C. Rosenow, Mayo Foundation, presented a paper on "Experimental Studies of the Etiology of Disease of the Nervous System" with lantern slide demonstration and with motion picture films of animals, demonstrating the symptoms produced by injection of material from patients with lethargic and other forms of encephalitis, epidemic hiccup, spasmodic tortocollis and chorea. This study was an extensive and comprehensive presentation of scientific experimental work. Louis Wilson, Mayo Foundation, presented a philosophic discussion of the needs of physicians under the title "Factors in the Continued Development of the Physicians."

The spring meeting of the society will be held in Long Beach on the first Friday and Saturday in April. The following officers were elected for the coming year. President, Robert Pollock, San Diego; First Vice President, Dr. F. L. Rogers, Long Beach; Second Vice President, Joseph Swindt, Pomona; Secretary-Treasurer, Egerton Crispin, Los Angeles.

Pharmacology and Therapeutics

Edited by FELIX LENGFELD, Ph. D.

During October the following articles have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Non-official Remedies:

Lederle Antitoxin Laboratories: Diphtheria Toxin-Antitoxin (0.1L†).

H. A. Metz Laboratories, Inc.: Alumnol.

H. K. Mulford Company: Hay Fever Timothy Pollen Extract-Mulford.

Parke, Davis & Co.: Normal Horse Serum—P. D. & Co., Rabies Vaccine (Cumming)—P. D. & Co.

E. R. Squibb & Sons: Acne Vaccine, Colon Vaccine—Squibb, Gonococcus Vaccine, Meningococcus Vaccine, Normal Horse Serum, Pertussis Vaccine, Curative; Pertussis Vaccine, Immunizing; Purified Diphtheria Antitoxin (Antidiphtheric Globulin), Pneumococcus Vaccine, Staphylococcus Vaccine, Stachylo-Acne Vaccine, Streptococcus Vaccine, Tetanus Antitoxin Purified, Typhoid Vaccine, Typhoid Vaccine Combined, Immunizing.

NEW AND NON-OFFICIAL REMEDIES

Hayfever Timothy Pollen Extract-Mulford—The liquid is obtained by extracting the protcins from the pollen of timothy. For a discussion of actions, uses and dosage, see the article on "Pollen and Epidermal Extracts Preparations and Biologically Reactive Food Proteins," New and Non-official Remedies, 1922, p. 232. This preparation is marketed in packages containing fifteen consecutive doses for a complete treatment and also in packages containing partial treatments only. H. K. Mulford Co., Philadelphia.

Purified Diphtheria Antitoxin (Antidiphtheria Globulin)—Concentrated diphtheria antitoxin (New and Non-official Remedies, 1922, p. 280), is marketed in syringe containers of 1000 units and in syringe containers of, respectivcly, 3000, 5000, 10,000 and 20,000 units. E. R. Squibb & Sons, New York.

Normal Horse Serum—This product (New and Non-official Remedies, 1922, p. 278) is also marketed in packages of one 10 cc. syringe. E. R. Squibb & Sons, New York. (Jour. A. M. A., Oct. 21, 1922, p. 1427.)

Aluminum Compounds—Several aluminum compounds are official, including the ardinary alum. The acetate and acetotartrate of aluminum are used in the form of solutions described in the National Formulary. Aluminum compounds are used for their astringent action. They are not so astringent as the lead salts, but they may exert an irritant and even caustic action when used in the form of concentrated solutions or as "burnt" alum. Aluminum compounds are slightly antiseptic. Proprietary preparations of aluminum in combination with organic acids have been introduced with a view of utilizing the astringent and antiseptic properties of their components.

Alumnol—The aluminum salt of betanaphtholdisulphonic acid. Alumnol is used as a mild antiseptic and, in concentrated solutions, as an irritant or caustic. It is used for the destruction of the gonococcus in gonorrhea. H. A. Metz Laboratories, Inc., New York.

Novocain Base—Para-amino-benzoxydiethylaminoethane. The base contained in procaine. The action and uses of novocain base are the same as those of procaine (New and Non-official Remedies, 1922, p. 36), but it is soluble in fixed oils. H. A. Metz Laboratories, Inc., New York.

Novocain Nitrate—A brand of procaine nitrate—N. N. R. (New and Non-official Remedies, 1922, p. 37). It has the actions and uses of procaine, but is compatible with silver salts. H. A. Metz Laboratories, Inc., New York.

Diphtheria Toxin-Antitoxin Mixture (0.1L†)—A diphtheria toxin-antitoxin mixture (New and Non-official Remedies, 1922, p. 282) containing 0.1 lethal dose of diphtheria toxin neutralized with the required amount of diphtheria antitoxin. Marketed in packages of three vials, each containing 1 cc.; also in packages of thirty vials, each containing 1cc. Lederle Antitoxin Laboratories, New York.

Acne Vaccine—Acne bacillus vaccine (New and Non-official Remedies, 1922, p. 298) is marketed in packages of four syringes containing, respectivelv. 50, 100, 250 and 500 million killed bacilli; in packages of four ampules containing, respectivcly, 50, 100, 250 and 500 million killed bacilli (with a syringe); in vials of 5 cc., 10 cc. and 20 cc., each cubic centimeter containing 1000 million killed bacilli. E. R. Squibb & Sons, New York.

Gonococcus Vaccine—This product (New and Non-official Remedies, 1922, p. 301) is marketed in packages of four syringes containing, respcctively, 100, 250, 500 and 1,000 million killed gonococci; in packages of four ampules containing, respectively, 100, 250, 500 and 1000 million killed gonococci (with a syringe); in vials of 5 cc., 10 cc. and 20 cc., each cubic centimeter containing 1000 million killed gonococci. E. R. Squibb & Sons. New York.

Meningococcus Vaccine, Curative—Meningococcus vaccine (New and Non-official Remedies, 1922, p. 302) is marketed in packages of four syringes containing, respectively, 100, 250, 500 and 1000 million killed meningococci; in packages of four ampules containing, respectively, 100, 250, 500 and 1000 million killed meningococci (with a syringe), and in vials of 5 cc., 10 cc. and 20 cc., each cubic centimeter containing 1000 million killed meningococci. E. R. Squibb & Sons, New York.

Pertussis Vaccine, Curative—Pertussis bacillus vaccine (New and Non-official Remedies, 1922, p. 303) is marketed in packages of four syringes containing, respectively, 100, 250, 500 and 1000 million killed bacilli; in packages of four ampules containing, respectively, 100, 250, 500 and 1000 million killed bacilli (with syringe), and in vials of 5 cc., 10 cc. and 20 cc., each cubic centimeter containing 2000 million killed bacilli. E. R. Squibb & Sons, New York.

Pertussis Vaccine, Immunizing—Pertussis bacillus vaccine (see New and Non-official Remedies, 1922, p. 303) is marketed in packages of three syringes containing, respectively, 500, 1000 and 1000 million killed bacilli; in packages of three ampules containing, respectivcly, 500, 1000 and 1000 million killed bacilli (with a syringe). E. R. Squibb & Sons, New York.

Pneumococcus Vaccine—This product (New and Non-official Remedies, 1922, p. 304) is a suspension of killed pneumococci, Types I, II, III, and Group IV in equal proportions. Marketed in packages of four syringes containing, respectivcly, 100, 250, 500 and 1000 million killed pneumococci; in packages of four ampules containing, respcctively, 100, 250, 500 and 1000 million killed pneumococci (with syringe), and in vials of 5 cc., 10 cc. and 20 cc., each cubic centimeter containing 5000 million killed pneumococci. E. R. Squibb & Sons, New York. (Jour. A. M. A., Oct. 28, 1922, p. 1519.)

PROPAGANDA FOR REFORM

Afsal—Afsal is being marketed by S. Lewis Summers. It is stated to be "diacetyl methylene disalicylic acid." The product was formerly marketed by the Organic Chemical Manufacturing Co. (S. Lewis Summers, president) as Urasol. Urasol was one of a number of the "Forma-Sol Compounds" marketed by the Organic Chemical Manufacturing Co. and stated to be compounds of methylene-disalicylic acid. Sollmann reported in 1908 in an investigation made for the Council on Pharmacy and Chemistry that he had been unable to confirm the claims that were made for these compounds. A subsequent examination confirmed Sollmann's findings. (Jour. A. M. A., Sept. 7, 1922, p. 1264.)

Spahlinger's Treatment for Tuberculosis—Spahl-

inger, according to reports, was a lawyer who abandoned his profession for research work. He appears now to be connected with the Bacterio-Therapeutic Institute, Geneva. According to an article by Spahlinger, the treatment utilized either one or both of two therapeutic principles, depending on the nature of the infection. In acute cases, passive immunization with special serums is used. In chronic afebrile pulmonary cases, in non-pulmonary, and in cases "predisposed to" tuberculosis, active immunization with special antigens is employed. No definite information in regard to the preparation of the product is given. Reports that the British Red Cross is to purchase the treatment are unconfirmed. Reports that the Rockefeller Institute had made an offer to secure the rights for the product in the United States proved unfounded. The exact nature of the Spahlinger treatment does not appear to have been divulged, the treatment is in the experimental stage and the reported results lack confirmation. (Jour. A. M. A., Oct. 7, 1922, p. 1264.)

Radioactivity of Waters—Twenty-five years ago various mineral springs and waters were claimed to have therapeutic virtues because of their lithium content. Today we know that the amount of lithium in natural waters is insignificant, and that lithium is of no therapeutic value anyway. At the present time many mineral waters are exploited because of their asserted content of radium. However, the rationale of the internal administration of radium is being doubted. Also, relative traces of radio-active substances are practically valueless and the Council on Pharmacy and Chemistry will not accept any radium solution for internal use the dosage of which is less than two micrograms each day or any radium emanation generator which yields less than two microcuries emanation each twenty-four hours. The probable value of radio-active mineral waters may be judged when it is known that it would be necessary to consume 2810 gallons daily of the water yielding the largest quantity of temporary radio activity in order to obtain the minimum therapeutic dose of two microcuries emanation and that the best water available as regards radium content would require the administration of 1957 gallons per day in order to obtain two micrograms of radium. (Jour. A. M. A., Oct. 14, 1922, p. 1339.)

The Clinical Field of Yeast Preparations—In March, 1921, the Council on Pharmacy and Chemistry requested its Committee on Therapeutic Research to determine the advisability of undertaking a clinical study of the usefulness in therapy of yeast preparations. Accordingly, the chairman of that committee drew up a provisional plan which proposed to utilize the easily observable phenomena of growth, appetite and laxative effect as cumulative indices of all actions and to record this under a variety of normal and pathologic conditions. The plan was submitted to the committee and to others for an opinion. In consideration of the replies received and the unfavorable results published by A. L. Daniels and by A. F. Hess, the chairman of the committee recommended that the study be not inaugurated. The chairman reported that he had come to these conclusions: 1. Apart from the occasional imported cases of beriberi vitamin deficiency is not a recognized or diagnosable clinical entity in this country. 2. With ordinary diet yeast does not have any effect on growth, even of babies and children. 3. The one effect of yeast that has been definitely established is the laxative effect. This may be useful in chronic constipation, but no direct method of study is at present available for determining its advantages or disadvantages in comparison with other laxatives. After considering the recommendations of its Research Committee, the Council for the present decided against an investigation into the problematic usefulness of yeast as a therapeutic agent. (Jour. A. M. A., Oct. 14, 1922, p. 1354.)

Arsenauro—Some ten to twenty years ago, this preparation had considerable vogue. It is believed to be similar in composition to solution of gold and arsenic bromid of the National Formulary. This contains bromid of gold and arsenic acid. Gold preparations were at one time believed to have therapeutic value, particularly as "alteratives." They have proved inefficient and have been discarded. (Jour. A. M. A., October 21, 1922, p. 1446.)

Clearo—This was a "patent medicine" sold by C. E. McCuistion, Dallas, Tex., doing business as "The Clearo Co.," as a cure for tuberculosis, asthma, bronchitis, hayfever, serious throat and lung troubles. An investigation by the postoffice authorities led to the conclusion that the product was worthless for the purposes claimed, and that the Clearo Co. was engaged in a scheme for obtaining money through the mails by means of fraud. The Clearo Co. has been denied the use of the mails. (Jour. A. M. A., Oct. 21, 1922, p. 1445.)

A Pancreatic Hormone in Diabetes—Since the discovery of the important role of the pancreas in carbohydrate metabolism in the body there have been many attempts to supply the missing "regulator" of sugar combustion, and attention has naturally been centered on the pancreas in this connection. Significant results have been secured in the Department of Physiology at the University of Toronto by J. J. R. Macleod and his collaborators. An alcoholic extract of pancreas has been prepared, which apparently enabled the diabetic animal and man to metabolize sugar better. The investigators are wisely withholding the product from general use until its value is definitely established. (Jour. A. M. A., Oct. 21, 1922, p. 1428.)

Typhoid Vaccination by Mouth—Besredka has proposed vaccination against typhoid by mouth. His vaccine consists of a pill of bile and a tablet containing a mixture of heat-killed typhoid and paratyphoid bacilli. These are taken three mornings in succession. It is for the future to determine whether or not the method has value. (Jour. A. M. A., Oct. 21, 1922, p. 1446.)

The Reactions of Boston to the "Reactions" of Abrams—Abrams gave a clinical demonstration of his methods in the laboratory of one of his disciples in Boston. Abrams refused to submit the method, it is said, to any test offered, but confined himself to demonstrating the presence of lesions, the existence of which would be proved only by post-mortem examination. A member of the staff of the Boston Medical and Surgical Journal, a man in perfect health, was selected for experiment. By his diagnostic methods, Abrams discovered in this healthy individual a streptococcus infection, tuberculosis of the intestinal tract, congenital syphilis, and intestinal sarcoma. Otherwise, the man was all right. It is understood that the volunteer inconsiderately refused to submit to a post-mortem examination. (Jour. A. M. A., Oct. 28, 1922, p. 1524.)

Susto—According to the trade package, Susto is a "Vitamin Tonic Food in Concentrated Form, Rich in the Vitamins of Rice, Eggs, Milk and Yeast, Notably rich in Fat Soluble and Water Soluble Vitamins A, B, C, together with Beef Proteins, Nucleins and Iron." Susto is put on the market by Chester Kent & Co., Boston, better known as the sellers of Vinol. Vinol was essentially an alcoholic tonic, containing unrecorded amounts of iron, manganese peptonates, iron and ammonium citrate, lime and soda glycerophosphate, beef and codliver peptone, cascarin and sodium silacylate and 18 per cent alcohol. Some years back Vinol was advertised as a codliver preparation without oil. Vinol seems to have been made for Chester Kent & Co. by Frederick Stearns & Co., the firm which made Stearn's Wine of Codliver Extract with Peptonate of Iron. When alcohol tonics were no longer good form, Chester Kent & Co. employed Philip B. Hawk, Professor of Physiologic Chemistry at Jefferson Medical College, Philadelphia to "perfect" a product that was sent him as Vinol

Powder. Hawk did this: He also furnished the company with clinical reports and experimental data that could be counted on as valuable advertising thunder. Thus was born Susto. Patent medicine exploiters are cognizant of the fact that the public can be more easily humbugged on the food tonic scheme than by any other, particularly so when they can get the active co-operation of men whose scientific training should put them above such things. For one dollar the purchasers will get a few cents' worth of food material.

"Dimol: A New Intestinal Antiseptic." (reported by R. F. Stratton, M. D., Oakland). "Probably other members of the profession have received pamphlets and trade notices concerning the above named English pharmaceutical in which the astonishing claim is made that it possesses a bactericidal power thirty-five times that of phenol, without irritating or toxic qualities. The range of usefulness of a therapeutic agent having such remarkable attributes is evident.

In its department "Reports and Analytical Records from the Lancet Laboratory" the issue of that journal for April 19, 1921, referring to dimol, appears the statement "Tests made for us confirm a coefficient of 35.0 and freedom from toxicity claimed by the manufacturers. In view of its importance, a further investigation and confirmation of this seemed justifiable, even desirable.

Special conditions rendered it inadvisable to await a report from the Council of Pharmacy of the American Medical Association, and at my request, the Western Laboratory of Oakland conducted a series of experiments, following the method of the Hygienic Laboratories, U. S. Public Health Service, showing that the specimen of the drug obtained by me in the open market and submitted to them for examination had a phenol coefficient, not of thirty-five (35.0) as announced, but only of eight-tenths (0.8).

Search of subsequent issues of the Lancet to that above mentioned fails to discover any later modifications of their report."

BUSINESS AND THE BUSY PHYSICIAN

Why not let our advertisers help you?

NEW ADVERTISERS

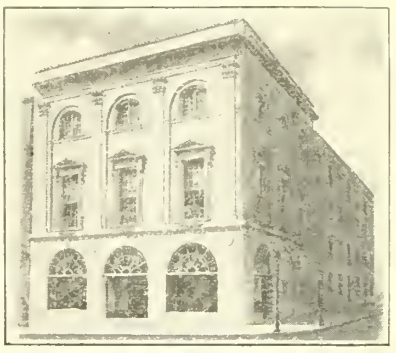
Among the new advertisers in this issue of the Journal are:

G. D. Searle & Co. of Chicago, whose Los Angeles representative is Paul McConnell, 1943 Bonsallo Ave. They have entered the California field with a line of tablets, ointments, liquids and other fine pharmaceuticals. They will be glad to furnish their catalogue and answer any other inquiries from physicians and hospitals.

Howard-Holt Company of Cedar Rapids, Iowa, announce themselves as chemists to the medical profession. Their advertisement of Siomine has been accepted by the Council on Pharmacy and Chemistry, and their advertisement as appearing in this issue of the Journal has been secured for us by the Co-operative Medical Advertising Bureau of the A. M. A.

The Cilkloid Co. announce in a one-half page advertisement in this issue of the Journal (which was secured for us by the Co-operative Medical Advertising Bureau) an improved impervious, perforated surgical dressing. The products of this company are for sale by local and surgical supply houses in Los Angeles and San Francisco. An old advertiser in the Journal dealing with the same line of goods is, Welton & Company, whose product is known as "Cellosilk."

Richter & Druhe, 604 Mission Street, San Francisco. This firm has recently opened offices in San Francisco and have a half page advertisement in this issue of the Journal. They are importers of European white enamel hospital and surgical ware. The quality of their goods, their methods of salesmanship and their integrity as a business house have been accepted by the committee controlling advertising columns of the Journal. They desire to make business contracts with hospitals and physicians. Other advertisers dealing with the same line of goods, who have been known to our readers for many months are, Reid Bros., 91-99 Drumm St., San Francisco; Geo. H. Ramage Co., 411-412 Bank of Italy Bldg., Fresno; Travers Surgical Co., 372 Sutter St., San Francisco; Walters Surgical Company, 441 Sutter St., San Francisco; Bischoff's Surgical House, Oakland; Frank S. Betz Co., Hammond, Ind.



The New Home of Hynson, Westcott & Dunning of Baltimore

This national drug firm has just erected and occupied its own building at Charles and Chase Streets, Baltimore. The building is artistic in appearance and adapted to accommodate the several departments of their rapidly developing business which began in a small way in 1889, but has now grown to a million a year, with an organization of 125 people. Their unique sales department alone comprises 19 men who visit physicians in all parts of the United States, but do not sell goods. Thirty-five of their products have been accepted by the Council, and are advertised in this Journal. None of their preparations is offered direct to the public but is introduced to the medical profession for the use of physicians and their patients. Mr. H. P. Hynson, one of the founders, died in 1921; but their growing business has now been established in new quarters under the immediate supervision of Messrs. James W. Westcott and H. A. B. Dunning (the latter being the active administrator) with a highly trained force, equipped to meet promptly the demands of the medical profession anywhere and at all times.

Abbott Laboratories Expand—The Abbott Laboratories of Chicago have purchased the Dermatological Research Laboratories of Philadelphia. This is an advance step for the Abbott Laboratories and will give them deserved recognition among the leading manufacturers of medicinal products. The Dermatological Research Laboratories were the first in the United States to produce Arsphenamine during the war when there was such a scarcity of this article; and these Laboratories became well known to the medical profession for their patriotic attitude in developing and manufacturing medicinal preparations in this country. By this purchase of "DRI" products, the Abbott Laboratories inherited their prestige. The Abbott Laboratories acquired control of the Dermatological Research Laboratories on November 1 and are continuing to operate them in Philadelphia under the direction of Dr. Geo. W. Raiziss, head of the department of Chemistry, and his corps of assistants.

CORRESPONDENCE

Ethan H. Smith comments on G. J. McChesney's article in the October issue of the Journal, subject, "The Modern Treatment of the Weak or Flat-Foot":

"In the October number of the California State Journal of Medicine, is a very excellent article by Dr. G. J. McChesney of San Francisco, on 'The Modern Treatment of the Weak or Flat-Foot.'

"I would like to consider a few of the points made by Dr. McChesney in his article.

"Dr. McChesney, together with many other orthopedic surgeons, seems to have overlooked some of the fundamental principles on which flat-foot should be handled. They confuse what might be termed the active stage of flat-foot, with what might be termed the active stage of flat-foot, with what might be termed the convalescent stage. They also lay too much stress on the arch of the foot, and do not give enough consideration to the accompanying condition in the muscles of the leg.

"The so-called 'spring ligament' has so few elastic fibres in it, that we can afford to forget them. The elasticity of the normal foot is not dependent on one ligament, but on the construction of the whole foot associated with the leg muscles, all of which are so arranged as to give a considerable elasticity to the foot and leg under normal conditions.

"We do not put splints on normal legs, yet we do put a support on a broken leg. So when the longitudinal arch of a foot is buckled inward, causing a marked abduction in the front of the foot on the head of the astragalus, and the corresponding abduction of the os calcis underneath the astragalus, and then the buckled arch rotates downward by the giving way of both tibial muscles, it is folly to talk of restoring this condition without correcting the deformity. The reason for that is, that we have too weakened and well-nigh useless, partially atrophic muscles incapable of performing their usual function, pitted against markedly contracted peronei muscles and also contracted calf muscles. Unless the arch is restored, and in severe cases placed in Plaster of Paris, and in milder cases held in position by a suitable support, we shall get nowhere with marked cases of flat-foot.

"We must also differentiate between the acquired flat-foot which has become distorted after having been normal during a great many years, and the real weak foot of childhood which is flat not because of overstrain and injuries such as cause the adult type of flat-foot, but because of the delayed ossification of the bones of the medio-tarsal region. These cases of weak-foot are by far more difficult to treat, and can never be restored by exercises, tilting of shoes, or any other such measures. They must be kept in position until such time as the bones have become thoroughly calcified and capable of carrying the weight of the patient's body, and also bearing the strain on the muscles in the act of locomotion.

Depending alone on the tilting of the heel and sole of the shoe, together with what should always be a convalescent treatment by massage and exercises, is likely to be just as successful as treating a broken leg without support of any kind from the date of injury. It will frequently result in arthritis, a metarso-phalangeal joint of the middle toe, a huge corn on this side, and corns on and between the third, fourth and fifth toes. Only this, and nothing more.

"Metal arch supports are an abomination. All of them, with one or two exceptions, are the shape of a bad flat-foot, and could not be endured for one-half hour if they were otherwise. Those that are not so are as comfortable as a steel trap on the foot, and that means, 'enough said.' The modeling of the foot for metal arch supports, as it is most frequently done, is a farce, and results in perpetuating the deformity. It also frequently augments the trouble by setting up a frightful arthritis in the inner portion of the medio-tarsal joint. It causes enlargement and thickening of the scaphoid and internal cuneiform bones, making them of such shape that they can never be restored to any semblance of the normal.

"Many of Dr. McChesney's ideas are good, but they are not applicable to the beginning of treatment of marked cases of flat-foot."

Dr. McChesney's reply to Dr. Smith's comments is as follows:

"I can agree in the main with Dr. Ethan Smith's ideas. I did not discuss the various kinds of flat-foot and treatment thereof in such detail as he would have liked, solely because the length of my paper was definitely restricted, as it was read at the Orthopedic Section meeting at the last State meeting, and I presented the basic factors of "The Modern Treatment of the Weak and Flat-Foot" the best I could in the fifteen minutes allotted. His emphasis upon my ideas regarding the importance of the leg muscles and the inadvisability of metal arch supports meets quite with my approval. Perhaps in exceptional cases a temporary arch support of some soft material is indicated as he infers, but the number of such exceptional cases is less than he would have us believe."

NEW MEMBERS

Alameda County: Childress, Hugo, Oakland; Crane, W. W. Jr., Oakland; Appeldorn, H. H., Piedmont; Fowler, Charles B., Oakland.

Fresno County: Pendergrass, James E., Clovis; Minas, Yervant, Fresno.

Los Angeles County: Ruth, Edward S., Los Angeles; Franklin, E. S., Los Angeles; James, Robert J., Los Angeles; Post, James O., Los Angeles; Brill, Wm., Los Angeles; McGee, Harry S., Los Angeles; Otto, Frank W., Los Angeles; Brandes, Leo, Los Angeles; Strathearn, H. J., Los Angeles; Munroe, Harrington B., Los Angeles; Webster, John C., Los Angeles; Brunig, H., Los Angeles; Miller, Allan P., Los Angeles; Chapman, James W., Pasadena; Tilton, Albert L., Los Angeles; Wallace, Alexander, Los Angeles; Hertzikoff, Sam, Los Angeles; Schmoele, John M., Los Angeles; Pomeroy, George T., Burbank; Harrison, Elake, Los Angeles; Sauer, Frank J., Bowers, Paul E., Los Angeles, Kegley, E. A., Los Angeles; Stevens, Harold E. E., Burbank; Gundrum, Willis H., Owensmouth; Magnusson, Herman V., Bell; Schaefer, J. W., Los Angeles; Crowell, T. C., Los Angeles; King, Ernest Harold, Los Angeles; Jones, George W., Los Angeles; Frisch, Adalbert, Los Angeles.

Transferred to L. A. County: Cox, Edward, to Los Angeles from Fresno; Dickson, G. G., to Los Angeles from Sacramento.

Monterey County: Lineer, A. S., Soledad.

Orange County: Crain, A. N., Santa Ana; Steen, E. J., Fullerton; Hollingsworth, M. W., Anaheim; Ball, D. R., Santa Ana; Harwood, D. W., Santa Ana; Farrage, J., Santa Ana.

San Diego County: Osborne, Albert, San Diego; Tow, Johanna E., San Diego; Newman, Willard H., San Diego.

San Francisco County: Kaarboe, Olav, San Francisco; Paul, Burton E., San Francisco.

Santa Barbara County: Culler, Robert M., Santa Barbara.

CURTIS GEORGE KENYON

The death of Curtis G. Kenyon marks the passing of one of San Francisco's pioneer surgeons. Doctor Kenyon was born in 1846 and received his degree of Doctor of Medicine from the College of the Pacific, November 4, 1873, and was licensed to practice in California September 19, 1876. He began his practice in San Francisco as Resident Physician at St. Mary's Hospital. He was an assistant to Dr. Levi Cooper Lane, under whom he received his surgical training. In 1889 Doctor Kenyon was appointed Visiting Surgeon to St. Luke's Hospital and continued as such until his retirement in 1919, acting for many years as Chief of Staff, and on his retirement was made Surgeon Emeritus.

He was an outstanding figure in all movements calculated to advance medical education, methods of practice, medical organization, and all other movements looking toward better public health and better medicine.

He was a member of many of the scientific societies to which physicians aspire; had filled practically all offices in local and State medical organizations, and had been for more than twenty years, without interruption and almost without absence from a meeting, Chairman of the Council of the Medical Society of the State of California.

He was an able surgeon, a splendid citizen and a useful member of society. Perhaps no physician in California had more friends and fewer enemies. He is survived by Mrs. Kenyon and two sons.

The death that terminated this useful life was the result of an automobile accident which occurred in Hollywood, where he was living with his son, the well known author of "Kindling" and other plays. He died at St. Vincent's Hospital, Los Angeles, November 8, 1922. The funeral services were held there on Monday, November 13, 1922. The pallbearers were Doctors T. C. Edwards of Salinas, C. Van Zwalenburg of Riverside, Henry C. Brainerd, W. T. McArthur, William Duffield and Clarence Toland of Los Angeles.

The medical profession and a host of friends suffer a distinct loss in the passing of Curtis G. Kenyon.

HAROLD P. HILL.

DEATHS

Bryant, C. W., Died at Tepic, Mexico, September, 1922, aged 64. He was a graduate of Hospital College of Medicine, Central University, Kentucky, 1888; and practiced his profession in Shasta County for thirty years, until he went to Mexico a few years ago.

Figgins, Daniel W., Died at San Diego, September 15, 1922, aged 69. Graduate of College of Physicians and Surgeons, Iowa, 1877; licensed in California, March 6, 1889.

Keys, Ernest Melford, Died at Alameda, November 2, 1922, aged 65. Graduate of College of Physicians and Surgeons, Iowa, 1878. Licensed in California November 6, 1889.

Kiger, Thomas C., died at Los Angeles, November 2, 1922, aged 87. He was a graduate of Western Medical College, Cleveland, Ohio, 1857. He came to California in 1876 and practiced in Ventura until 1881, when he moved to Los Angeles, where he has actively followed his profession for 41 years.

Prather, Demetrius J., Died at Laton, California, October 5, 1922, aged 73. Graduate of Louisville Medical College, Kentucky, 1876. Licensed in California February 11, 1898.

Scott, Charles L., Died at Hanford, California, September 4, 1922, aged 49. Graduate of Keokuk Medical College, Iowa, 1898. Licensed in California January 3, 1899.

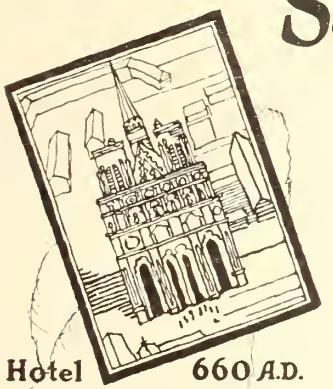
Shine, Francis E., Died September 8, 1922, in the American Hospital in Neville, France, aged 51. He was a graduate of the University of Virginia, 1895. Doctor Shine was chief surgeon of the El Paso and Southwestern Railroad from 1903 to 1920, and chief surgeon of the Phelps Dodge Corporation, Bisbee, Arizona, 1903 to 1920. He was licensed in California November 3, 1920, and resided in Los Angeles at the time of his death, having gone to France only a short time before on a vacation. He was a member of the Los Angeles County Medical Society, State Medical Society, American Medical Association, and other medical organizations, and was a major, M. C., U. S. Army.

Trueworthy, John Wesley, Died in Los Angeles, September 10, 1922, aged 69. He was a graduate of University of Michigan and received his M. D. degree from Rush Medical College, 1865. He had practiced medicine in Los Angeles for thirty years, having retired from active practice only two years ago. He was a member of the Los Angeles County Medical Society; the State Medical Society and the American Medical Association.

Warren, H. S., Died in Yreka, California, September 21, 1922, aged 39. He was a graduate of Cooper Medical College, 1905, and began the practice of medicine at Montague in 1906. He later practiced in Coalinga and San Francisco, but returned to Humboldt County, where he remained until his death. He was superintendent of the County Hospital at the time of his death, and was a member of the Humboldt County Medical Society and the State Medical Society.

Weldon, William A., Died at San Pedro, September 7, 1922, aged 59. Graduate of Medical Department Bowdoin College, Maine, July 6, 1884. He came to California in the same year and had resided in San Pedro almost continuously from that time until his death, being closely identified with the growth and development of Los Angeles County. He was a member of the Los Angeles County Medical Society and the State Medical Society.

Paris *in* 660 *and* San Francisco *in* 1921



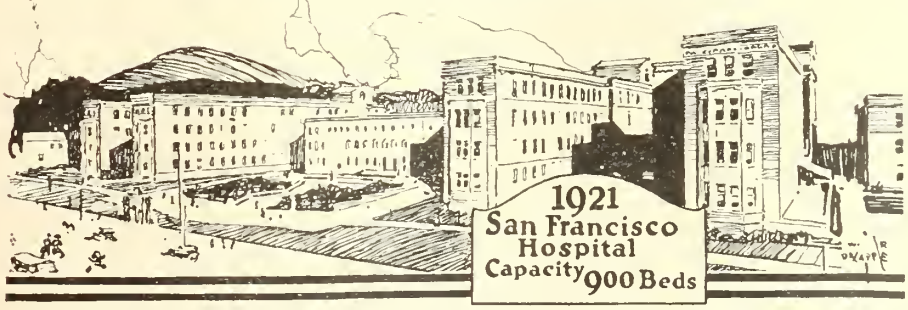
Hotel Dieu Hospital, Paris 660 A.D.
Capacity 194 Beds
(From an old wood cut)

Typifying the hospital of mediaeval ages, Hotel Dieu, built in Paris in 660 A.D., is representative. In those days, wards were heated with charcoal stoves; patients slept on mattresses of straw thrown over a network of ropes; pillows were knots of twisted cloth. Hospitals were few, poorly equipped and sanitary conditions deplorable.

Progress in hospitals was negligible until late in the 19th century when their use became more universal. In the United States in 1873 there were but 149 hospitals. Today there are over 9000, an increase of over 6000%. In 1920, there were over 8,000,000 patients of hospitals. The investment in hospital grounds and buildings is over three billion dollars. Purchases for equipment and supplies exceeded a billion dollars last year, more than the sales of cigars and cigarettes, or candies and confections.

The business of furnishing these institutions with supplies has taken equally rapid strides. **REID BROS., Inc.,** the foremost company in the world manufacturing, jobbing and exporting hospital supplies, has grown from a business of $20,000 in 1909 to one of one million. Its goods are now standard throughout the United States and 83 foreign countries. So rapidly is the available business increasing that the company finds its manufacturing and distributing facilities inadequate to handle it. To take advantage of these possibilities the company is now building at Irvington, Alameda County, one of the largest hospital supply factories in the world.

A new issue of 2000 shares of ***REID BROS., Inc.*** *common stock is now being offered at $100 par value. Each share has full voting power and is non-assessable. Dividends are payable quarterly, have never paid less than 8%, and are free from Normal Individual Federal Income Tax.*



1921 San Francisco Hospital Capacity 900 Beds

Securities of REID BROS., Inc. have never paid less than 8% since the establishment of the Company. Its common shares, now offered, have paid as high as 12, 14 and 18%. This consistent dividend-paying record has been maintained in good times and bad, evidencing the stability of the hospital supply business and REID BROS., Inc. Net earnings have more than taken care of dividend requirements with provision for a substantial annual reserve fund besides. Securities of REID BROS., Inc. are readily marketable. They have a high value as borrowing collateral. Owners of stock may convert their shares into cash within 30 days through the company's securities department.

Send now for further information. Ask how you can earn 6% interest while paying for your shares on monthly installment plan.

OVALTINE

In Pregnancy and Lactation

There are many reasons for the widespread use of "Ovaltine" in the diet of maternity. Physicians the world over recognize its value not only as an effective means of promoting the flow and quality of the milk of the nursing mother but as a form of nutriment ideally adapted to prenatal requirements.

"Ovaltine" has a marked galactagogue action attributed to its richness in maltose and other food principles having specific galactagogue qualities and also to the fact that these principles are almost completely absorbed with minimum digestive disturbance. The use of "Ovaltine," commenced during the later stages of gestation and continued throughout the nursing period, materially aids in promoting the general health of the mother enabling her to withstand the extra strain imposed upon the system.

For similar reasons "Ovaltine" is a valuable adjunct to the diet during the whole period of pregnancy. It counteracts any tendency to constipation, and in cases of vomiting, clinical experience has shown that it is well retained when ordinary forms of nourishment are rejected by the patient.

"Ovaltine" is taken as a delicious beverage which can be prepared at a moment's notice without bother, mess or trouble of any kind.

Samples and literature mailed to physicians upon signed request.

Supplied by druggists at 50c, 80c, $1.50 and $5.00.

HYDROPATHIC DEPARTMENT

COTTAGE DEPARTMENT

THE LIVERMORE SANITARIUM

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the U. S.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) $45.00 per week and upward.

Radiographic Room

Selecting An X-Ray Machine

THE physician who decides to apply the X-Rays in his general practice requires more than a machine. What are the technical resources of the company that makes the machine? How far does that company co-operate with the medical profession in devising apparatus that meet its requirements? Is the company in a position to aid the practitioner with technical advice? Is it prepared to maintain its apparatus in perfect operative condition?

Clearly, the physician must deal with a manufacturer of X-Ray equipment who realizes that his responsibility does not end with the installation of a machine and who is governed by the standards that the medical profession observes in its dealings with the public.

Victor X-Ray apparatus is made by a company whose research facilities are unsurpassed. The history of the X-Ray in medicine is practically the history of Victor apparatus. Hardly a year passes but the Victor Research Laboratories develop an improvement that enables the physician to use X-Rays with greater effectiveness.

The Victor X-Ray Corporation feels that its responsibility does not end with the installation of one of its machines. It maintains Service Stations in the principal cities—stations which the physician may call upon for technical assistance at a moment's notice and for repairs.

Physicians who install Victor apparatus are kept informed of the latest developments in X-Ray technique through "Service Suggestions," a publication which is issued from time to time by the Victor X-Ray Corporation and distributed gratuitously.

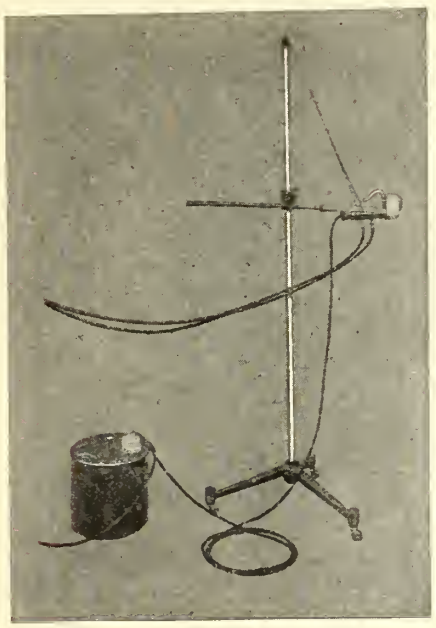
Resident physician. X-Ray equipment. Complete laboratory and operating room service. Any member of A. M. A. can attend his own patients here if he wishes. Ideal for convalescent, chronic and rest-cure cases of all types. Competent staff and consultants available if desired.

THE SANITARIUM WITH A PERSONALITY

Address all communications to Medical Director, Ross Sanitarium, Ross, California

THE pride of the craftsman in his handiwork is exemplified in the zeal with which Parke, Davis & Company's pharmaceutical chemists, biologists, and physiologists maintain the unvarying quality of Adrenalin. And that quality is the natural result of highly specialized scientific skill, gained through twenty years' experience in the manufacture of the original product.

THE NAME "ADRENALIN" IS LINKED INSEPARABLY WITH THE GOOD NAME OF PARKE, DAVIS & COMPANY



THE KROMAYER LAMP

Consider—

that the Kromayer lamp enjoys the distinction for highest intensity of Ultra-Violet radiation and the most practical means for administering treatment of many conditions.

The effective results obtained with its use over a period of ten years has been the stimulant for our scientific research work that has resulted in bringing the lamp to its present high state of efficiency.

It is chosen as the most desirable method of applying actinic rays to Lupus, Naevus, Acne, Psoriasis, Eczema, Ulcers and Wounds; to specific or non-specific orificial inflammatory conditions such as Tubercular Laryngitis, Rectal Fistulae, Otitis Media, Frontal Sinus Infections, Ozena and a number of gynecological conditions.

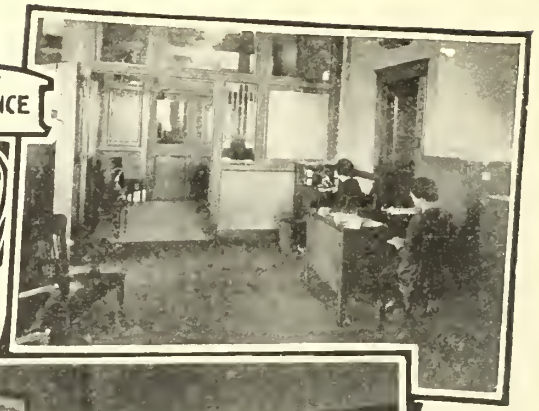
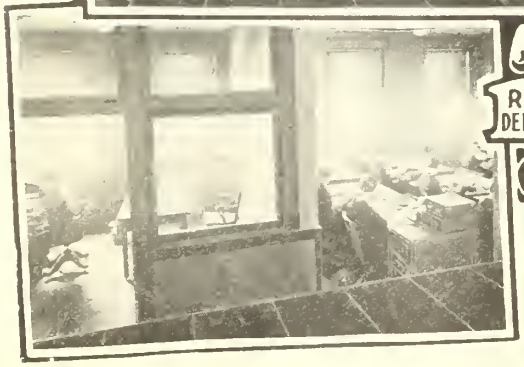
OFFICERS AND DIRECTORS

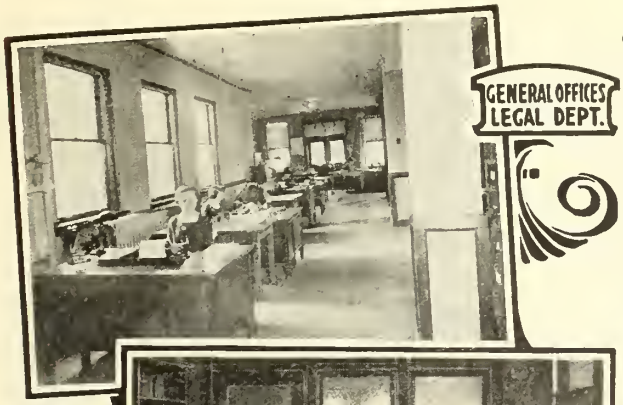
CHARLES M. NIEZER
CHIEF of LEGAL STAFF

There are certain fundamental principles of sound business endeavor which dictate existence and decide success. Necessity must make the industry of primary importance and of permanent value.

The laws regulating the practice of medicine and dentistry, as well as the natural unpreventable hazards, gives primary importance to an organization of our kind. Specialized Service has induced a success which cannot but impress an appreciation of the dependence of the professions upon the permanent value of The Medical Protective Company.







The quality, reliability, promptness and accuracy of service depends upon the facilities for work. The science of Medical Jurisprudence and its skillful application enters into the defense of all claims and suits; and to these essentials are constantly being added the experience of continuous practice and the study and solution of new problems, to the end that the finished service may at all times be most efficient in operation and endurance.

The Medical Protective Company has risen to leadership because its clients have confidence in its judgment and faith in its integrity.

THE MEDICAL PROTECTIVE CO.
OF FORT WAYNE, INDIANA

THE complicated technic incident to the preparation of solutions of Arsphenamine with the attendant danger of improper alkalization as well as the rapidity with which the Arsphenamine oxidizes and forms toxic compounds during the preparation of the solution, make it apparent that the widespread use of this product is dependent upon the development of a safe and ready-to-use solution.

The Squibb Laboratories therefore take pleasure in announcing that they have ready for distribution

Solution Arsphenamine Squibb

Prepared according to the process devised by Dr. Otto Lowy; licensed by the U. S. Public Health Service and approved by the Council on Pharmacy and Chemistry of the American Medical Association.

READY FOR IMMEDIATE USE.

Solution Arsphenamine Squibb offers the advantages of accuracy in preparation, perfect alkalization, and safety in use.

It avoids the danger of oxidation with the consequent formation of toxic oxidation products, and it eliminates the necessity for costly apparatus and the loss of time spent in preparing solutions.

Solution Arsphenamine Squibb is a scientifically prepared solution of Arsphenamine. It is in no sense a substitute for Arsphenamine.

Solution Arsphenamine Squibb is marketed in 80 Cc. and 120 Cc. ampuls with all necessary attachments, ready for administration.

E·R·SQUIBB & SONS, NEW YORK

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858.

Colfax School for the Tuberculous

Experience has shown that Sanatorium treatment is the most efficient and most approved method of treating the tuberculous. Those patients who are able to take advantage of the superior facilities offered by sanatorium treatment should not be denied the opportunity of receiving these benefits.

The cottage colony of the Colfax School for the Tuberculous provides accommodations for patients who have not only all the advantages of the sanatorium regime and supervision but at the same time have the benefit of home cooking and surroundings. While the patient improves the other members of the family daily receive instructions relative to those things everyone should know regarding tuberculosis.

Information regarding the methods of treatment and other details of interest to the physician and his patient are given in a booklet which will be sent on request.

Address all communications to

A Bloodless Field

is promptly produced by the application or hypodermatic injection of

Suprarenalin Solution, 1:1000

—the stable and non-irritating preparation of the Suprarenal active principle. The e. e. n. and t. men find it the premier product of the kind.

Ischemia follows promptly the use of 1:10000 *Suprarenalin Solution* slightly warmed (make 1:10000 solution by adding 1 part of Suprarenalin Solution to 9 parts of sterile normal salt solution).

In obstetrical and surgical work *Pituitary Liquid* (Armour), physiologically standardized, gives good results—½ c. c. ampoules obstetrical—1 c. c. ampoules surgical. Either may be used in emergency.

Elixir of Enzymes is a potent and palatable preparation of the ferments active in acid environment—an aid to digestion, corrective of minor alimentary disorders and a fine vehicle for iodides, bromides, salicylates, etc.

As headquarters for the organotherapeutic agents, we offer a full line of Endocrine Products in powder and tablets (no combinations or shotgun cure-alls).

LABORATORY PRODUCTS

Armour's *Sterile Catgut Ligatures* are made from raw material selected in our abattoirs, plain and chromic, regular and emergency lengths, iodized, regular lengths, sizes 000—4.

Subscription prices, including postage, per annum in advance: Domestic, $4.00; Canadian, $5.00.

Domestic rates include United States, Cuba, Mexico, Hawaii, Guam, Porto Rico, Canal Zone and Philippine Islands.

Acceptance for mailing at special rate of postage provided for in Section 1103, Act of October 3, 1917, authorized August 10, 1918.

SINGLE COPIES of this calendar year, 50 cents.

REMITTANCES should be made by check, draft, registered letter, money or express order. **Currency should not be sent unless the letter is registered.** Stamps in amounts under one dollar are acceptable. Make all checks etc., payable to "Medical Society, State of California."

VOLUMES begin with the first of January. Subscriptions may commence at any time.

CHANGE OF ADDRESS notice should give both the old and the new address, and state whether the change is permanent or temporary. The change notice must reach us ten days in advance of the date of the issue which is to be forwarded to the new address.

WARNING: Pay no money to an agent unless he presents a letter showing authority for making collection.

ADVERTISEMENTS.

Advertising forms go to press fifteen days in advance of the date of issue. In sending in copy time must be allowed for setting up advertisements and for sending proofs. No proprietary medicines can be advertised until approved by the Council on Pharmacy and Chemistry. Advertising rates will be sent on request.

CONTRIBUTIONS.

EXCLUSIVE PUBLICATION: Articles are accepted for publication on condition that they are contributed solely to this journal.

CONTRIBUTIONS TYPEWRITTEN: Authors must have their contributions typewritten—double-spaced and with ample margins—before submitting them. The expense is small to the author—the satisfaction is great to the editor and printer. We cannot promise to return unused manuscript, but try to do so in every instance. **Manuscript should not be rolled.**

ILLUSTRATIONS: Half-tones and zinc etchings, if necessary to elucidate the text, will be furnished by The Journal when satisfactory photographs or drawings are supplied by the author. Each illustration, table, etc., should bear the author's name on the back. Photographs should be clear and distinct; drawings should be made in black ink on white paper. While we cannot guarantee to return used photographs and drawings, we use our best endeavors to do so after the article is published, if the word "return" is written on the back of each.

ANONYMOUS CONTRIBUTIONS, whether for publication, for information, or in the way of criticism, are consigned to the wastebasket unread.

NEWS: Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to physicians. We shall be glad to know the name of the sender in every instance.

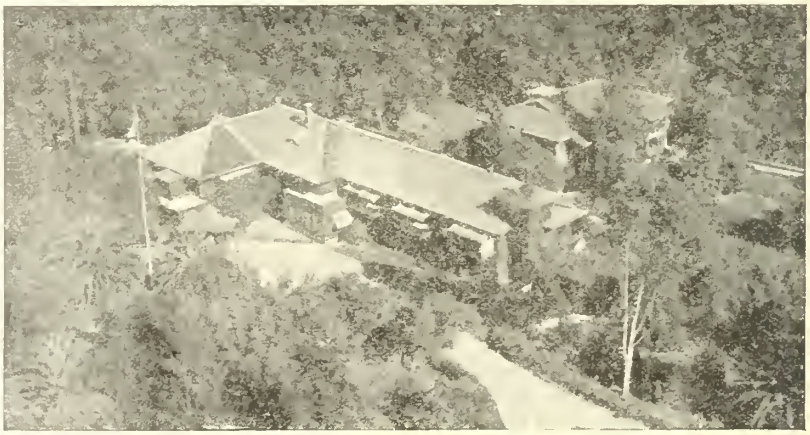
AIRPLANE VIEW OF GROUNDS

A SANITARIUM FOR THE TREATMENT OF ALL FORMS OF NERVOUS DISORDERS AND GENERAL DISEASES

SIXTEEN MILES FROM LOS ANGELES, HEART OF THE ORANGE BELT



MAIN BUILDING

LOCATION—Situated in the foothills of the Sierra Madre Mountains, just outside of the city of Pasadena, is this beautiful sanitarium. It is surrounded by a natural live-oak grove of 20 acres, with lawns and gardens, ideally adapted to rest and enjoyment. Large central building and cottages all modernly equipped. Homelike and comfortable.

Climate Ideal.
Cuisine Excellent.
Outdoor Sports and Recreation.

EQUIPMENT—Special equipment for aiding in a correct diagnosis. The Laboratory, Hydrotherapy and Electricity Departments are important adjuncts to the general Sanitarium treatment. All forms of baths are given, including the famous Nauheim.

Dairy and Poultry Plant.
Rooms With or Without Baths.
Private Bungalows With Sleeping Porches.

CLASS OF PATIENTS — All forms of nervous disorders and general diseases are treated. Special attention is paid to Gastro-Intestinal disorders and Circulatory System. No Tuberculosis, Epilepsy or Insanity received.

BOARD OF DIRECTORS — Norman Bridge, M. D., H. C. Brainerd, M. D., W. Jarvis Barlow, M. D., F. C. E. Mattison, M. D., Stephen Smith, M. D.

Dr. King's Sanatorium

(THE BANNING SANATORIUM)

Banning (Riverside County) California

This well known institution (for the treatment of tuberculosis of the throat and chest) has recently been rebuilt and enlarged. The City of Banning (suffering from phthisiophobia) passed a "zoning" ordinance that forced abandonment of the former site of this sanatorium. A new site was purchased. An injunction was sought to prevent the use of the new site for sanatorium purposes. A temporary injunction was granted but, at the final hearing, this injunction was dissolved and the right to build and maintain the sanatorium was established. Many of the most prominent physicians in the state contributed testimony that enabled us to win the suit. During the progress of these suits the institution found it difficult to provide for patients demanding admission. Now, however, in its new quarters, it is prepared to accept all who apply. To physicians who are unfamiliar with our work we will gladly furnish references to other physicians (in almost every town in California) who have had patients or relatives in this institution. A circular describing conditions and containing rates will be mailed upon request. Address

DRS. KING and BRAMKAMP. BANNING, CALIFORNIA.

DIRECTLY and INDIRECTLY

Liquid Peptonoids

IS AN IMPORTANT NUTRITIONAL AID IN THE SICK ROOM

DIRECTLY

BECAUSE it is acceptable when all other food is rejected *and* offers immediately available nitrogen *and* calories — in sufficient amounts to be *of* real importance in emergency feeding—THEREBY saving tissue waste *and* preventing collapse.

INDIRECTLY

BECAUSE it sets the digestive pendulum in motion, kindles the appetite *and* creates food tolerance — THUS speeding the moment when more substantial nourishment may be added to the dietary.

Also DRY PEPTONOIDS (Soluble). 40% Protein—51.5% Carbohydrate.

RADIUM
AND
ONCOLOGIC INSTITUTE

1151 WEST SIXTH STREET
LOS ANGELES

A THOROUGHLY EQUIPPED INSTITUTION affording unexcelled facilities for the scientific administration of Radium Therapy and the study and treatment of Neoplastic diseases.

THE NEW AND MODERN FIREPROOF BUILDING contains private rooms for bed and ambulatory cases, completely equipped examination and treatment rooms, Roentgen Ray, clinical and research laboratories.

THE RADIUM LABORATORY, in addition to a large and adequate quantity of Radium, is equipped with a Duane emanation apparatus and all necessary appliances, affording the most modern and complete facilities for Radium Therapy.

THIS INSTITUTION, substantially endowed, is in its equipment and capacity equal to any other in this country, and is the largest and most complete in the United States, devoted exclusively to this work.

WE DESIRE TO CONFER and cooperate with the medical profession regarding the use of Radium in appropriate cases.

THE BABY CLARKE is appropriately named. It is a portable gas outfit which the physician can very well take with him as part of his obstetrical equipment. There is constant and legitimate call from women patients that some of the terrors of obstetrical pain be relieved. It is the common practice now in hospitals to use gas for this purpose. THE BABY CLARKE will render the same service to the obstetrician and may be carried to the patient's home and used there or anywhere else.

The portable apparatus is automatic, and requires no attention in analgesia, also used in minor operations. Most progressive men are using Nitrous Oxid-Oxygen in their Obstetrics.

DOES NOT DISTURB THE PATIENT

Made in two parts, simply, yet strongly connected, the Gwin-Flex stretcher can be readily removed without disturbing the patient. In many post-operative conditions the use of this stretcher insures not only greater comfort for the patient, but likewise far greater safety.

The two parts of the Gwin-Flex Stretcher are held together by a flexible steel tape which is easily removed, enabling both parts of the stretcher to be withdrawn without disturbing the patient. The stretcher is readily sterilized as the handles and tape are removable. The stretcher is extremely strong, although light in weight. Particularly convenient in turning sharp angles and passing through doorways.

May we send you full particulars, together with list of prominent hospitals now using the Gwin-Flex Stretcher?

Burnett Sanitarium

Fresno, California

For those patients demanding the use of Radium and X-Ray we are in a position to offer to the medical profession the full and unqualified services of our laboratory. This laboratory is equipped with both Radium element and a complete Emanation plant which enables us to construct any application we may desire to fit the given case. To those physicians wishing to make their own application we are prepared to serve with Radium emanation as they may direct.

Address Dr. D. H. Trowbridge,

Secretary Burnett Sanitarium Co.

CALCREOSE

CALCREOSE (calcium creosote) is a mixture containing in loose chemical combination approximately equal weights of creosote and lime. It has all the pharmacologic activity of creosote but has no untoward effects on the stomach; therefore it may be taken in comparatively large doses for long periods of time.

In the treatment of acute inflammations of the respiratory tract and infections of the gastro-intestinal tract CALCREOSE has been used with good success.

CALCREOSE can be given in comparatively large doses for long periods of time without any objection on the part of the patient.

Reibro Sterile Tube Catgut Does Not Tangle

We were not satisfied with selling the best tube catgut the market offered—we knew there was need for improvement. After considerable research work we are now able to offer the hospitals and profession of the world catgut of our own manufacture embodying the following indispensable improvements:

The catgut is so coiled in the tube that both ends project and will not tangle. A new tubing fluid is used which evaporates from the gut immediately after removal from the tube and leaves no residue. Ideal, flat knots are made with it. Perfect sterility is assured. We control the gut from the animal to the tube. Put up in compact, handy boxes.

Your surgery cannot afford to be without the improvements embodied in this catgut. Its quality and performance is fully backed by our responsibility. A fair trial is all we ask — it will win its own way afterwards.

Gonorrheal Infections

INVOLVING deep-seated tissues, especially arthritis (gonorrheal rheumatism), prostatitis, epididymitis and posterior urethritis are conditions in which

Glycerol-Vaccine

Gonococcus

Lederle

affords encouraging results.

Note: The Glycerol-Vaccines were introduced by the LEDERLE ANTITOXIN LABORATORIES early in 1920 and have since given uniformly consistent results of a satisfactory nature.

Advantages

It will not deteriorate. It is free from autolytic products.

Large doses can be tolerated without systemic reaction.

Marked improvement in arthritis cases after the first four or five doses.

Gonococci rapidly disappear from the urethral discharges.

Administration

Glycerol-Vaccine

Gonococcus

Lederle

is supplied in 15 concentrated serially numbered graduated doses.

Each dose is accompanied by a vial of sterile diluent with which dilution is made immediately before hypodermic administration, thus ensuring the potency of the vaccine.

WHOOPING-COUGH *causes more deaths*

under one year of age than any other infectious disease. In America more than 10,000 children die each year of whooping-cough

Glycerol-Vaccine

Pertussis

Lederle

is of value for the prevention and treatment of whooping-cough. The average duration of the disease under vaccine treatment is about 3½ weeks, while under other forms of treatment the average duration is from 9 to 12 weeks.

MILLER states (American Journal of Public Health, October, 1921):

"Whooping-cough vaccine is the only therapeutic measure worthy of consideration in the treatment of this disease. * * *

"I believe that public health authorities are justified in promoting immunization against whooping cough just as they are urging immunization against typhoid fever."

MADE IN THE GOOD OLD U. S. A.

A Thoroughly Soft, Pliable, Transparent

DRESSING MATERIAL

Cellosilk is a product developed by American Science to meet the long felt need of the medical profession for a suitable dressing of this kind. It is prepared from Cotton, Gums, and carefully blended, is suitable for all dressing purposes.

PERFORATED AND IMPERVIOUS FORMS

Impervious Cellosilk is used as a protective covering over all wet and moist dressings, as a direct Impervious dressing where such is indicated, and for drains.

Perforated Cellosilk is used as a direct, non-adherent dressing for all granulating wounds; burns, skin grafts, ulcers, mastoid operations, etc.

Secure Cellosilk from your regular supply house. Both Perforated and Impervious forms should be on hand at all times for use as needed.

Marshalltown Laboratories, Inc. **Marshalltown, Iowa.**

HOSPITAL FOR CHILDREN AND TRAINING SCHOOL FOR NURSES

A general hospital of 275 beds for women and children.
Thirty beds for maternity patients in a separate building, newly equipped.

Complete services of all kinds for women and children.
Infant feeding a specialty.

House staff consists of three resident physicians and eight internes.

Accredited by the Council on Medical Education and Hospitals of the American Medical Association.

Institutional member of League for the Conservation of Public Health.

The oldest school of nursing in the West.

OVALTINE

In Pregnancy and Lactation

There are many reasons for the widespread use of "Ovaltine" in the diet of maternity. Physicians the world over recognize its value not only as an effective means of promoting the flow and quality of the milk of the nursing mother but as a form of nutriment ideally adapted to prenatal requirements.

"Ovaltine" has a marked galactagogue action attributed to its richness in maltose and other food principles having specific galactagogue qualities and also to the fact that these principles are almost completely absorbed with minimum digestive disturbance. The use of "Ovaltine," commenced during the later stages of gestation and continued throughout the nursing period, materially aids in promoting the general health of the mother enabling her to withstand the extra strain imposed upon the system.

For similar reasons "Ovaltine" is a valuable adjunct to the diet during the whole period of pregnancy. It counteracts any tendency to constipation, and in cases of vomiting, clinical experience has shown that it is well retained when ordinary forms of nourishment are rejected by the patient.

"Ovaltine" is taken as a delicious beverage which can be prepared at a moment's notice without bother, mess or trouble of any kind.

Samples and literature mailed to physicians upon signed request.

Supplied by druggists at 50c, 80c, $1.50 and $5.00.

HYDROPATHIC DEPARTMENT

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

COTTAGE DEPARTMENT

THE LIVERMORE SANITARIUM

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the U. S.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) $45.00 per week and upward.

Address Livermore Sanitarium, Livermore, Calif.

WILL THE MANUFACTURER OF YOUR X-RAY APPARATUS STAY IN BUSINESS?

THE physician who buys an X-Ray equipment buys not only to meet present but future needs. Will the manufacturer who delivers his equipment be in business five, ten years hence? If not, who is to supply parts? Who is to make repairs?

The Victor X-Ray Corporation is as old as the X-Ray. Its past is a sufficient guarantee of its future. It is the oldest manufacturer of X-Ray equipment in the United States. It has maintained from the very beginning a Service organization whose duty it is to respond to the call of Victor users when their equipment needs attention—a Service organization which has been systematically expanded until now it includes the principal cities of the United States. It occupies a dominant position, because it devoted its energies not only to manufacturing the best possible X-Ray equipment, but also to improving that equipment through research.

The Victor X-Ray Corporation is a permanent institution. In dealing with it the physician has the assurance that not only is he purchasing the best apparatus that scientific research has been able to produce at the time, but that it will be kept in operative condition by a manufacturing company that will continue to exist and to meet his demand for repair and maintenance service.

THE SANITARIUM WITH A PERSONALITY

Address all communications to Medical Director, Ross Sanitarium, Ross, California

THE pride of the craftsman in his handiwork is exemplified in the zeal with which Parke, Davis & Company's pharmaceutical chemists, biologists, and physiologists maintain the unvarying quality of Adrenalin. And that quality is the natural result of highly specialized scientific skill, gained through twenty years' experience in the manufacture of the original product.

THE NAME "ADRENALIN" IS LINKED INSEPARABLY WITH THE GOOD NAME OF PARKE, DAVIS & COMPANY

THE ALPINE SUN LAMP

THE Alpine Sun Lamp illustrated above presents the most convenient source of intense Ultra-Violet Light known at the present time.
Its field of indications covers Tuberculosis in most of its manifestations, superficial skin lesions, nervous diseases, post-operative infections, osteomyelitis, sluggish ulcers, and conditions resulting from faulty metabolism.

Standard

SINCE the advent of the Alpine Sun Lamp over a decade ago the high standard set for it has always been upheld.

Long researches by us and clinical tests made by users, have made this lamp an instrument of physical and mechanical precision, particularly typified by the model shown in the accompanying illustration.

And the consistent good work continues!

MODERN AIDS IN URINALYSIS

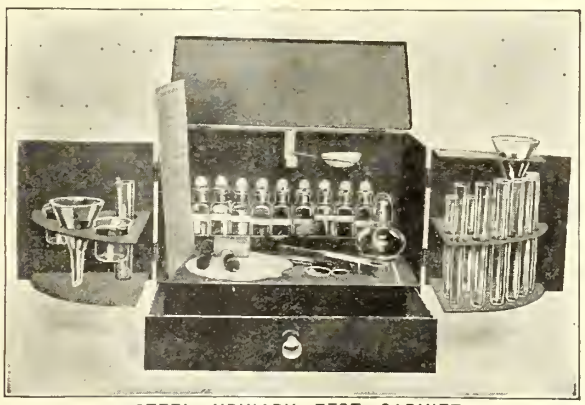
Very often the Physician in general practice is handicapped by lack of suitable equipment for making the simpler tests in laboratory diagnosis. We offer at reasonable prices three modern aids in office laboratory diagnosis at reasonable prices.

THE NEW URINARY TEST CABINET

NO MORE WOOD—IT'S ALL STEEL NOW

AN EXCLUSIVE BETZCO PRODUCT

The new Betzco Urinary Test Cabinet is quite complete for office urinalysis. Although wood urinalysis outfits are to be found on the market, this outfit with its steel cabinet is an exclusive Betzco product and decidedly superior to outfits with wood cabinets. It is cleaner, sturdier, and more compact. It is finished in smooth olive green enamel that is washable. All equipment folds into it readily. The top of the cabinet lifts up; the front is divided into two swinging doors and there is a large drawer below.



STEEL URINARY TEST CABINET

COMPLETE WITH FULL DIRECTIONS

Each test cabinet comes complete with full directions and equipment as follows: Nine reagents in glass stoppered bottles; alcohol lamp; porcelain evaporating dish; two funnels; two beakers; assorted test tubes; urinometer; urinometer jar; wood test tube holder; watch glasses; glass stirring rod; litmus paper and graduated pipette. With this outfit the Physician is able to make the simpler examinations of urine in his own office, observing the exact reactions which take place.

2CJ219. Steel Urinary Test Cabinet.....$11.00

Speedy Electrical Centrifuges

WITH PERFECT SPEED CONTROLS

Much time and trouble have been involved in perfecting our two and four arm electric centrifuges. In offering the finished product to the profession, it is with the firm conviction that both types will prove highly efficient and thoroughly satisfactory for office and general laboratory work.

FOUR ARM ELECTRIC CENTRIFUGE

This equipment is supplied with a universal motor, operating on either direct or alternating current. The motor is mounted in a dust proof casing with heavy cast base provided with lugs for fastening to laboratory table or sink. The rheostat is scientifically constructed and worked out to give the operator perfect control of the speed. When in service on direct current, this centrifuge has a speed of from 900 to 2,400 RPM; when in service on alternating current, it has a speed of from 800 to 1,900 RPM.

The equipment for the four arm centrifuge includes four aluminum shields, two plain glass 15 CC. (Mil.) tapered sediment tubes and two 15 CC. (Mil.) graduated percentage tubes and special removable four arm head.

9CJ4216. Four Arm Electric Centrifuge, for 110 volt direct or alternating current **$30.00**
Motor wired for service on 32, 40 or 220 volt current, extra..... 5.00

TWO ARM ELECTRIC CENTRIFUGE

This equipment is constructed similarly to the four arm machine, being fully as efficient and embodying the same devices for control. It is built with a slightly smaller motor of sufficient capacity to carry the two arm head at the same speed as the larger motor used in the four arm equipment. It is equipped with two aluminum tube shields, one 15 CC. (Mil.) plain glass sediment tube and one 15 CC. (Mil.) graduated percentage tube.

9CJ4215. Two Arm Electric Centrifuge, for 110-volt direct or alternating current, complete..... **$25.00**
Motor wired for service on 32, 40 or 220 volt current, extra.. 5.00

This Washer Will Do the Work of Four

This No. **115** Solid Head "Rapid" will do the work of four ordinary old style machines. It will do its work in less time and require less of every item that enters into the washing process.

The laundry in which it is in operation will be run more economically and efficiently — and the work will be better.

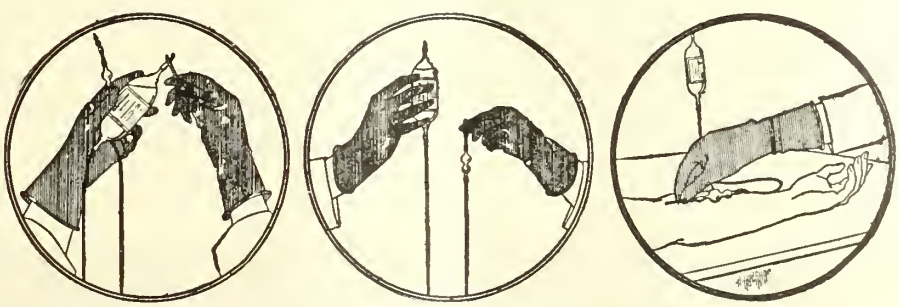
THE complicated technic incident to the preparation of solutions of Arsphenamine with the attendant danger of improper alkalization as well as the rapidity with which the Arsphenamine oxidizes and forms toxic compounds during the preparation of the solution, make it apparent that the widespread use of this product is dependent upon the development of a safe and ready-to-use solution.

The Squibb Laboratories therefore take pleasure in announcing that they have ready for distribution

Solution Arsphenamine Squibb

Prepared according to the process devised by Dr. Otto Lowy; licensed by the U. S. Public Health Service and approved by the Council on Pharmacy and Chemistry of the American Medical Association.



READY FOR IMMEDIATE USE.

Solution Arsphenamine Squibb offers the advantages of accuracy in preparation, perfect alkalization, and safety in use.

It avoids the danger of oxidation with the consequent formation of toxic oxidation products, and it eliminates the necessity for costly apparatus and the loss of time spent in preparing solutions.

Solution Arsphenamine Squibb is a scientifically prepared solution of Arsphenamine. It is in no sense a substitute for Arsphenamine.

Solution Arsphenamine Squibb is marketed in 80 Cc. and 120 Cc. ampuls with all necessary attachments, ready for administration.

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858.

Colfax School for the Tuberculous

Experience has shown that Sanatorium treatment is the most efficient and most approved method of treating the tuberculous. Those patients who are able to take advantage of the superior facilities offered by sanatorium treatment should not be denied the opportunity of receiving these benefits.

The cottage colony of the Colfax School for the Tuberculous provides accommodations for patients who have not only all the advantages of the sanatorium regime and supervision but at the same time have the benefit of home cooking and surroundings. While the patient improves the other members of the family daily receive instructions relative to those things everyone should know regarding tuberculosis.

Information regarding the methods of treatment and other details of interest to the physician and his patient are given in a booklet which will be sent on request.

A Bloodless Field

is promptly produced by the application or hypodermatic injection of

Suprarenalin Solution, 1:1000

—the stable and non-irritating preparation of the Suprarenal active principle. The e. e. n. and t. men find it the premier product of the kind.

Ischemia follows promptly the use of 1:10000 *Suprarenalin Solution* slightly warmed (make 1:10000 solution by adding 1 part of Suprarenalin Solution to 9 parts of sterile normal salt solution).

In obstetrical and surgical work *Pituitary Liquid* (Armour), physiologically standardized, gives good results—½ c. c. ampoules obstetrical—1 c. c. ampoules surgical. Either may be used in emergency.

Elixir of Enzymes is a potent and palatable preparation of the ferments active in acid environment—an aid to digestion, corrective of minor alimentary disorders and a fine vehicle for iodides, bromides, salicylates, etc.

As headquarters for the organotherapeutic agents, we offer a full line of Endocrine Products in powder and tablets (no combinations or shotgun cure-alls).

LABORATORY PRODUCTS

Armour's *Sterile Catgut Ligatures* are made from raw material selected in our abattoirs, plain and chromic, regular and emergency lengths, iodized, regular lengths, sizes 000—4.

Butler Bldg., 135 Stockton St., San Francisco, California Phone Douglas 62

Subscription prices, including postage, per annum in advance: Domestic, $4.00; Canadian, $5.00.

Domestic rates include United States, Cuba, Mexico, Hawaii, Guam, Porto Rico, Canal Zone and Philippine Islands.

Acceptance for mailing at special rate of postage provided for in Section 1103, Act of October 3, 1917, authorized August 10, 1918.

SINGLE COPIES of this calendar year, 50 cents.

REMITTANCES should be made by check, draft, registered letter, money or express order. **Currency should not be sent unless the letter is registered.** Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Medical Society, State of California."

VOLUMES begin with the first of January. Subscriptions may commence at any time.

CHANGE OF ADDRESS notice should give both the old and the new address, and state whether the change is permanent or temporary. The change notice must reach us ten days in advance of the date of the issue which is to be forwarded to the new address.

WARNING: Pay no money to an agent unless he presents a letter showing authority for making collection.

ADVERTISEMENTS.

Advertising forms go to press fifteen days in advance of the date of issue. In sending in copy time must be allowed for setting up advertisements and for sending proofs. No proprietary medicines can be advertised until approved by the Council on Pharmacy and Chemistry. Advertising rates will be sent on request.

CONTRIBUTIONS.

EXCLUSIVE PUBLICATION: Articles are accepted for publication on condition that they are contributed solely to this journal.

CONTRIBUTIONS TYPEWRITTEN: Authors must have their contributions typewritten—double-spaced and with ample margins—before submitting them. The expense is small to the author—the satisfaction is great to the editor and printer. We cannot promise to return unused manuscript, but try to do so in every instance. **Manuscript should not be rolled.**

ILLUSTRATIONS: Half-tones and zinc etchings, if necessary to elucidate the text, will be furnished by The Journal when satisfactory photographs or drawings are supplied by the author. Each illustration, table, etc., should bear the author's name on the back. Photographs should be clear and distinct; drawings should be made in black ink on white paper. While we cannot guarantee to return used photographs and drawings, we use our best endeavors to do so after the article is published, if the word "return" is written on the back of each.

ANONYMOUS CONTRIBUTIONS, whether for publication, for information, or in the way of criticism, are consigned to the wastebasket unread.

NEWS: Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to physicians. We shall be glad to know the name of the sender in every instance.

PNEUMOCOCCUS ANTIGEN

PARTIALLY AUTOLYZED PNEUMOCOCCI

FOR THE TREATMENT OF PNEUMONIA

Prepared according to the method of Dr. E. C. Rosenow,
now of the Mayo Foundation, Rochester, Minnesota

A polyvalent antigen for subcutaneous use in the treatment of primary infections due to pneumococci of the various types with resulting clinical pneumonia.

The distinctly favorable impressions reported by many physicians and the constantly increasing demand for the product support the belief that in Pneumococcus Antigen is to be had a measure of able assistance in combating pneumococcus infections. Supplied only in 5 c.c. rubber-capped vials (20 billion partially autolyzed pneumococci in each c.c.).

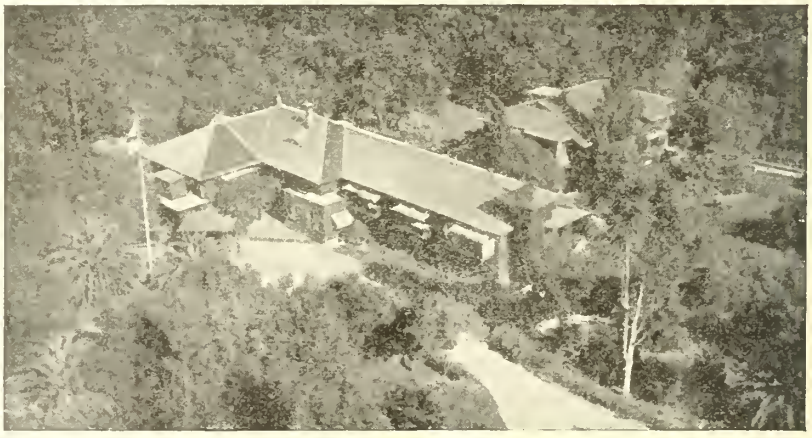
AIRPLANE VIEW OF GROUNDS

A SANITARIUM FOR THE TREATMENT OF ALL FORMS OF NERVOUS DISORDERS AND GENERAL DISEASES

SIXTEEN MILES FROM LOS ANGELES, HEART OF THE ORANGE BELT



MAIN BUILDING

LOCATION—Situated in the foothills of the Sierra Madre Mountains, just outside of the city of Pasadena, is this beautiful sanitarium. It is surrounded by a natural live-oak grove of 20 acres, with lawns and gardens, ideally adapted to rest and enjoyment. Large central building and cottages all modernly equipped. Homelike and comfortable.

Climate Ideal.
Cuisine Excellent.
Outdoor Sports and Recreation.

EQUIPMENT—Special equipment for aiding in a correct diagnosis. The Laboratory, Hydrotherapy and Electricity Departments are important adjuncts to the general Sanitarium treatment. All forms of baths are given, including the famous Nauheim.

Dairy and Poultry Plant.
Rooms With or Without Baths.
Private Bungalows With Sleeping Porches.

CLASS OF PATIENTS — All forms of nervous disorders and general diseases are treated. Special attention is paid to Gastro-Intestinal disorders and Circulatory System. No Tuberculosis, Epilepsy or Insanity received.

BOARD OF DIRECTORS — Norman Bridge, M. D., H. C. Brainerd, M. D., W. Jarvis Barlow, M. D., F. C. E. Mattison, M. D., Stephen Smith, M. D.

Las Encinas, Pasadena, Calif.

Dr. King's Sanatorium

(THE BANNING SANATORIUM)

Banning (Riverside County) California

This well known institution (for the treatment of tuberculosis of the throat and chest) has recently been rebuilt and enlarged. The City of Banning (suffering from phthisiophobia) passed a "zoning" ordinance that forced abandonment of the former site of this sanatorium. A new site was purchased. An injunction was sought to prevent the use of the new site for sanatorium purposes. A temporary injunction was granted but, at the final hearing, this injunction was dissolved and the right to build and maintain the sanatorium was established. Many of the most prominent physicians in the state contributed testimony that enabled us to win the suit. During the progress of these suits the institution found it difficult to provide for patients demanding admission. Now, however, in its new quarters, it is prepared to accept all who apply. To physicians who are unfamiliar with our work we will gladly furnish references to other physicians (in almost every town in California) who have had patients or relatives in this institution. A circular describing conditions and containing rates will be mailed upon request. Address

DRS. KING and BRAMKAMP. BANNING, CALIFORNIA.

DIRECTLY and INDIRECTLY

Liquid Peptonoids

IS AN IMPORTANT NUTRITIONAL AID IN THE SICK ROOM

DIRECTLY

BECAUSE it is acceptable when all other food is rejected *and* offers immediately available nitrogen *and* calories — in sufficient amounts to be *of* real importance in emergency feeding—THEREBY saving tissue waste *and* preventing collapse.

INDIRECTLY

BECAUSE it sets the digestive pendulum in motion, kindles the appetite *and* creates food tolerance — THUS speeding the moment when more substantial nourishment may be added to the dietary.

Also DRY PEPTONOIDS (Soluble). 40% Protein—51.5% Carbohydrate.

THE ARLINGTON CHEMICAL COMPANY

RADIUM
AND
ONCOLOGIC INSTITUTE

1151 WEST SIXTH STREET
LOS ANGELES

A THOROUGHLY EQUIPPED INSTITUTION affording unexcelled facilities for the scientific administration of Radium Therapy and the study and treatment of Neoplastic diseases.

THE NEW AND MODERN FIREPROOF BUILDING contains private rooms for bed and ambulatory cases, completely equipped examination and treatment rooms, Roentgen Ray, clinical and research laboratories.

THE RADIUM LABORATORY, in addition to a large and adequate quantity of Radium, is equipped with a Duane emanation apparatus and all necessary appliances, affording the most modern and complete facilities for Radium Therapy.

THIS INSTITUTION, substantially endowed, is in its equipment and capacity equal to any other in this country, and is the largest and most complete in the United States, devoted exclusively to this work.

WE DESIRE TO CONFER and cooperate with the medical profession regarding the use of Radium in appropriate cases.

THE BABY CLARKE is appropriately named. It is a portable gas outfit which the physician can very well take with him as part of his obstetrical equipment. There is constant and legitimate call from women patients that some of the terrors of obstetrical pain be relieved. It is the common practice now in hospitals to use gas for this purpose. THE BABY CLARKE will render the same service to the obstetrician and may be carried to the patient's home and used there or anywhere else.

The portable apparatus is automatic, and requires no attention in analgesia, also used in minor operations. Most progressive men are using Nitrous Oxid-Oxygen in their Obstetrics.

DOES NOT DISTURB THE PATIENT

Made in two parts, simply, yet strongly connected, the Gwin-Flex stretcher can be readily removed without disturbing the patient. In many post-operative conditions the use of this stretcher insures not only greater comfort for the patient, but likewise far greater safety.

The two parts of the Gwin-Flex Stretcher are held together by a flexible steel tape which is easily removed, enabling both parts of the stretcher to be withdrawn without disturbing the patient. The stretcher is readily sterilized as the handles and tape are removable. The stretcher is extremely strong, although light in weight. Particularly convenient in turning sharp angles and passing through doorways.

May we send you full particulars, together with list of prominent hospitals now using the Gwin-Flex Stretcher?

Burnett Sanitarium

Fresno, California

For those patients demanding the use of Radium and X-Ray we are in a position to offer to the medical profession the full and unqualified services of our laboratory. This laboratory is equipped with both Radium element and a complete Emanation plant which enables us to construct any application we may desire to fit the given case. To those physicians wishing to make their own application we are prepared to serve with Radium emanation as they may direct.

Address Dr. D. H. Trowbridge,

Secretary Burnett Sanitarium Co.

CALCREOSE

CALCREOSE (calcium creosote) is a mixture containing in loose chemical combination approximately equal weights of creosote and lime. It has all the pharmacologic activity of creosote but has no untoward effects on the stomach; therefore it may be taken in comparatively large doses for long periods of time.

In the treatment of acute inflammations of the respiratory tract and infections of the gastro-intestinal tract CALCREOSE has been used with good success.

CALCREOSE can be given in comparatively large doses for long periods of time without any objection on the part of the patient.

Directory of Endorsed Advertisers

It is the purpose of the Journal to develop on this page a classified list of advertisers who do not care to insert display advertisements. The same censorship will be applied to these advertisements as is now used in the reading columns and other advertising columns of the Journal. The space will be limited to five lines and advertisements will all be uniform in size and type. Suitable headings or classifications will be arranged as required. No advertisements will be accepted for less than six months, and the rates are $2.00 per issue.

Gonorrheal Infections

INVOLVING deep-seated tissues, especially arthritis (gonorrheal rheumatism), prostatitis, epididymitis and posterior urethritis are conditions in which

Glycerol-Vaccine

Gonococcus

Lederle

affords encouraging results

Note: The Glycerol-Vaccines were introduced by the LEDERLE ANTITOXIN LABORATORIES early in 1920 and have since given uniformly consistent results of a satisfactory nature.

Advantages

It will not deteriorate. It is free from autolytic products.

Large doses can be tolerated without systemic reaction.

Marked improvement in arthritis cases after the first four or five doses.

Gonococci rapidly disappear from the urethral discharges.

Administration

Glycerol-Vaccine

Gonococcus

Lederle

is supplied in 15 concentrated serially numbered graduated doses.

Each dose is accompanied by a vial of sterile diluent with which dilution is made immediately before hypodermic administration, thus ensuring the potency of the vaccine.

WHOOPING-COUGH *causes more deaths*

under one year of age than any other infectious disease. In America more than 10,000 children die each year of whooping-cough

Glycerol-Vaccine

Pertussis

Lederle

is of value for the prevention and treatment of whooping-cough. The average duration of the disease under vaccine treatment is about 3½ weeks, while under other forms of treatment the average duration is from 9 to 12 weeks.

MILLER states (American Journal of Public Health, October, 1921):

"Whooping-cough vaccine is the only therapeutic measure worthy of consideration in the treatment of this disease. * * *

"I believe that public health authorities are justified in promoting immunization against whooping cough just as they are urging immunization against typhoid fever."

San Francisco Polyclinic and Post-Graduate Medical School

Founded 1889 1535 Jackson Street

ANNOUNCEMENT OF COURSES IN SURGERY

The San Francisco Polyclinic and Post-Graduate College has reorganized its teaching staff for the purpose of resuming post-graduate instruction that was interrupted by the World War. San Francisco, on account of its central location, its great hospitals and Universities, offers unrivaled facilities for graduates in medicine to obtain opportunities for post-graduate study. The first systematic course will be in Surgery and Allied Specialties, and will begin Monday, April 3, 1922, and continue for four weeks. Applicants must be graduates of a regular medical school and must have had previous surgical experience.

SYNOPSIS OF COURSE

OPERATIVE SURGERY—The surgical anatomy of each operation to be studied will be first carefully demonstrated. The operation will then be done by the student, first on the cadaver and then on the living dog. Twenty-four 2-hour periods will be allowed for this part of the course.

CLINICAL SURGERY—Four forenoons will be spent in the Surgical Amphitheatre and the operations performed will be carefully demonstrated to the students.

TONSIL SURGERY—Four 2-hour periods will be used in teaching this branch.

FRACTURES—Three 2½-hour periods will be used in the demonstration of the non-operative treatment of fractures by the methods evolved during the recent war. This will be supplemented by evening work on the technique of making and adjusting splints and casts.

ORTHOPEDICS—Four evening periods will be devoted to practical studies on the diagnosis and cure of the various conditions that produce backache, and on the anatomy and derangements of the knee, hip and shoulder joints.

UROLOGY—Four 1-hour demonstrations in the hospital and four 1-hour demonstrations in the clinic will be devoted to practical points in the diagnosis and treatment of genito-urinary diseases.

PROCTOLOGY—Four 1-hour periods will be given to the study of Proctoscopic diagnosis and treatment of rectal diseases.

ROENTGENOLOGY—Four 2-hour periods and two evening periods will be given to the study of X-Ray plates and radio-therapy.

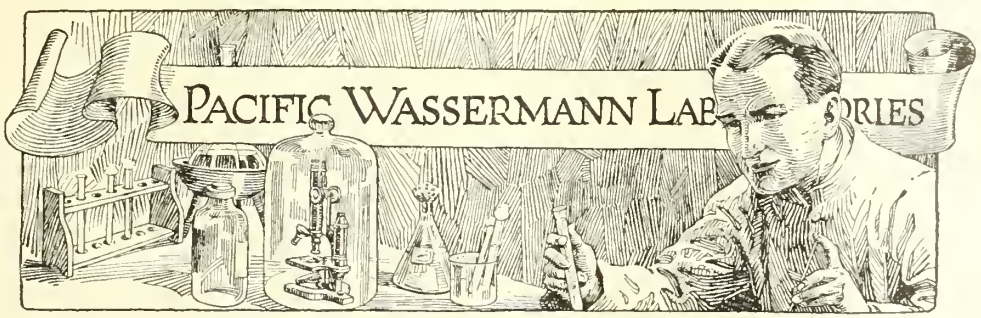
MISCELLANEOUS—A number of evening periods will be given to the discussion of practical points in pre- and post-operative treatment, obstetrics, gynecology, plastic, reconstructive and industrial surgery, and the relationship of physiology to surgery.

SCHEDULE

	8 to 9	9 to 10	10 to 11	11 to 12	1 to 2	2 to 3	3 to 4	8
Mon.	Operations on Dogs, Dr. Ryfkogel 8:30 to 11			Proctology, Dr. A. J. Zobel	Surgical Clinics			Splints Technique, Dr. Bunnell Goitre, Gastric Ulcer, Dr. Ryfkogel
Tue.	Neurology, Dr. Freyermuth	Tonsil Surgery, Dr. Pietrafesa		Urology, Dr. Stevens	Surgical Anatomy, Cadaver Surgery, Drs. Remmell, Callison and Casper			Physiology, Dr. Power Gynecology, Dr. Herzog
Wed.	Operations on Dogs, Dr. Bunnell 8:30 to 11			Industrial Surgery, Dr. Harbaugh		Radium-therapy Radio-therapy, Dr. Rodenbaugh		Backache, Anatomy and Derangement of Joints, Dr. Watkins
Thur.	Clinical Surgery Dr. Ryfkogel				Surgical Anatomy, Cadaver Surgery, Drs. Remmell, Callison and Casper			Plastic and Reconstructive Surgery, Dr. Pierce Obstetrics, Dr. Martin
Fri.	Operations on Dogs, Dr. S. N. Jacobs 8:30 to 11				Surgical Clinics			Roentgenology, Dr. Crowe Post-operative Treatment, Dr. Jacobs
Sat.	Fractures, Drs. Pierce and Bunnell 8:30 to 11			Urology, Dr. Hartman	Surgical Anatomy, Cadaver Surgery, Drs. Remmell, Callison and Casper			

The instruction in these courses will be practical in character, and is not intended to develop specialists but to add to the practical knowledge of those medical practitioners who are already doing their own surgery. The number of students will be limited to four, and the fee per student will be $250. For further information and enrollment blanks, apply to

H. A. L. RYFKOGEL, M. D., 516 Sutter Street, San Francisco



Our Policy and Ethics

The fundamental principle upon which this institution is founded is the maintenance of the highest standard of clinical laboratory service and efficiency. Accuracy is our watchword and no effort is ever spared to insure this. It is also our constant endeavor to uphold the highest ideals of ethical laboratory practice.

We contend that the clinical laboratory is a distinct and integral part of the physician's armamentarium and that the relation of laboratory practice to the general practice of medicine is as definite as the relation between the various specialties.

It is our conviction from years of practical experience that the highest efficiency in clinical laboratory specialization is attained by strictly confining the efforts and activity of the laboratory and its corps of trained specialists solely to laboratory work, removing the staff entirely from the field of medical treatment and practice. It is our very sincere belief that, in justice to the active medical practitioner and for the attainment of the greatest degree of efficiency in clinical laboratory specialization, the practice of medicine and laboratory practice as a specialty should be kept distinct and not combined.

Our staff is made up of experienced men with degrees in medicine and the sciences. Medical men of wide experience and training direct the pathological and medical work of these laboratories and the profession is invited to consult with them regarding the interpretation of laboratory findings. Our laboratory service is offered to the profession only. We do not invite specimens from the public.

It is upon these principles that the Pacific Wassermann Laboratories solicit the patronage of the medical profession. It is his laboratory and we are ready at all times to serve him ethically, conscientiously and with all due regard for his interests.

The Management of an Infant's Diet

Infants' Stools

Regularity in bowel movements contributes much toward normal, healthful progress, and a knowledge of the number and character of the stools during each twenty-four hours is an important part of the general management of early life and assists much in properly adjusting the diet.

Suggestions for the regulation of infants' stools by slight changes in the make-up of the diet and particularly in relation to

Constipated Movements

are given in our book, "Formulas for Infant Feeding," and in a pamphlet devoted especially to this subject. This literature will be sent to physicians who are interested in the matter.

HYDROPATHIC DEPARTMENT

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

COTTAGE DEPARTMENT

THE LIVERMORE SANITARIUM

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the U. S.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) $45.00 per week and upward.

JUDGING THE FUTURE BY THE PAST

THE present Victor X-Ray Corporation is the result of a rapid growth of a business established soon after the X-Rays were discovered. It is therefore practically as old as the X-Ray art.

The Victor X-Ray Corporation has always made it their purpose not only to manufacture and install, but to develop apparatus, to follow it into the very hands of the physician and maintain it in perfect operative condition on request, and to advance the scientific application of the X-Rays according to approved medical methods.

The past speaks for itself. No other manufacturer of X-Ray equipment has contributed so much to the advancement of X-Ray technique, to the training of Service and field representatives, to the education of the medical profession as a whole in the proper manipulation of X-Ray devices, and to the perfection of tubes and current-controlling devices.

This record of co-operation with the medical profession, extending over a period of nearly thirty years, is a guarantee of the future. Only an organization backed up by research such as that which the Victor X-Ray Corporation has built up, an organization with also a history of achievement behind it, is able to assure the physician who uses X-Rays in his practice that ten or twenty years hence it will continue to serve him by developing new technical aids, by assisting him to make the most of the apparatus that it places at his hands, and by co-operating with the most skilled roentgenologists in meeting the medical needs of the time.

IODALBIN

a protein-iodine compound for internal administration

THE therapeutic effects for which you prescribe iodides are produced most readily by those iodine compounds that are easily split up in the body. It is the available iodine that does the work.

In the case of Iodalbin, contact with the intestinal juice severs the loose bonds that unite the iodine with the protein base.

That's what makes Iodalbin rapidly effective.

And besides being effective, its blandness makes it acceptable to sensitive patients. It is especially gratifying to those who object to the taste and nauseating effect of sodium or potassium iodide.

A fair average dose for such cases as pleuritic effusion, dry bronchitis, lead poisoning, chronic rheumatic arthritis and the minor degrees of hypothyroidism, is 5 grains, repeated three or four times a day. Even in certain other diseases—cases requiring much larger doses, such as tertiary syphilis and myxedema—Iodalbin can be given with a minimum of discomfort to the patient.

Parke, Davis & Company

Supplied as a powder in ounce vials and in 5-grain capsules.

OVALTINE

In Pregnancy and Lactation

There are many reasons for the widespread use of "Ovaltine" in the diet of maternity. Physicians the world over recognize its value not only as an effective means of promoting the flow and quality of the milk of the nursing mother but as a form of nutriment ideally adapted to prenatal requirements.

"Ovaltine" has a marked galactagogue action attributed to its richness in maltose and other food principles having specific galactagogue qualities and also to the fact that these principles are almost completely absorbed with minimum digestive disturbance. The use of "Ovaltine," commenced during the later stages of gestation and continued throughout the nursing period, materially aids in promoting the general health of the mother enabling her to withstand the extra strain imposed upon the system.

For similar reasons "Ovaltine" is a valuable adjunct to the diet during the whole period of pregnancy. It counteracts any tendency to constipation, and in cases of vomiting, clinical experience has shown that it is well retained when ordinary forms of nourishment are rejected by the patient.

"Ovaltine" is taken as a delicious beverage which can be prepared at a moment's notice without bother, mess or trouble of any kind.

Samples and literature mailed to physicians upon signed request.

Supplied by druggists at 50c, 80c, $1.50 and $5.00.

Camp Curry Bungalow and Half Dome.

WE, OF CAMP CURRY, who have known Yosemite for nearly a quarter of a century, in sun and moonlight and shadow, playing host to 150,000 people, bid you welcome to explore its riches.

From the moment the first ray of sunlight strikes aslant Half Dome until the last glow of the Firefall fades from the stark black cliff behind Camp Curry, your days are filled with the pure joy of living.

The Pioneer Camp in Yosemite, Camp Curry has earned a world-wide reputation for giving the public the most possible for the money.

Comfort is everywhere—in the azalea hedged tents, in the charming rustic bungalows with their complete appointments, and in the central buildings with their boulder-set fireplaces—all in the midst of a forest of pine and fir and cedar, at the head of the valley, nearest the trails.

The personal hospitality of the owners, the days and evenings of companionship with interesting people from all over the world; nights by the Camp Fire with entertainment clever and jolly and worthwhile—the evening dance with partners in every garb, ungrudging service from a corps of intelligent and courteous young college people—all these go to make Camp Curry the Camp of Camps.

For the State Convention in May

Members and friends of the Medical Society of California planning to attend the State Convention, May 15-18, are invited to make their reservations now for accommodations at Yosemite Lodge.

These accommodations include Redwood Cottages with private baths at $7.50 a day, American plan, or Redwood and Canvas Cabins without bath at $5.50 a day, American plan. A European plan service is provided at $1.50 a day.

Visitors coming by rail will find a convenient train service via Merced to El Portal, where the comfortable green cars of the Yosemite Transportation System complete the journey with a delightful ride through Merced River Canyon.

During the Convention daily tours to the Mariposa Grove of Big Trees and around the floor of the Valley will be operated by the Yosemite Transportation System.

For reservations and full information write us at 637 Pacific Building, or apply to either of the addresses given below.

To the Medical Profession and Hospitals:

We invite you to call and acquaint yourselves with our NEW store—its personnel—its lines of new merchandise in standard made American, French and other instruments we know will have your approval—latest designs of W. D. Allison Company's office furniture—Wappler Electric Company's X-Ray treatment and diagnostic instruments—Scanlan Morris Company's hospital furniture.

Our repair shop and service station is well equipped and work is handled under the personal supervision of a factory representative direct from New York. You will find he understands "what to do" and "how to do it," and will make your service troubles matters of small importance.

Get acquainted with your new neighbor and fellow worker

The Best Method of Drying

This Troy Hot Air Dryroom Tumbler will dry everything except collars and shirts. It does its work in less time and with less expense than any other method of drying.

It does the work of the ordinary dryroom in half the time. All you have to do is to put the goods in the cylinder and start the machine.

THE complicated technic incident to the preparation of solutions of Arsphenamine with the attendant danger of improper alkalization as well as the rapidity with which the Arsphenamine oxidizes and forms toxic compounds during the preparation of the solution, make it apparent that the widespread use of this product is dependent upon the development of a safe and ready-to-use solution.

The Squibb Laboratories therefore take pleasure in announcing that they have ready for distribution

Solution Arsphenamine Squibb

Prepared according to the process devised by Dr. Otto Lowy; licensed by the U. S. Public Health Service and approved by the Council on Pharmacy and Chemistry of the American Medical Association.

READY FOR IMMEDIATE USE.

Solution Arsphenamine Squibb offers the advantages of accuracy in preparation, perfect alkalization, and safety in use.

It avoids the danger of oxidation with the consequent formation of toxic oxidation products, and it eliminates the necessity for costly apparatus and the loss of time spent in preparing solutions.

Solution Arsphenamine Squibb is a scientifically prepared solution of Arsphenamine. It is in no sense a substitute for Arsphenamine.

Solution Arsphenamine Squibb is marketed in 80 Cc. and 120 Cc. ampuls with all necessary attachments, ready for administration.

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

Colfax School for the Tuberculous

Experience has shown that Sanatorium treatment is the most efficient and most approved method of treating the tuberculous. Those patients who are able to take advantage of the superior facilities offered by sanatorium treatment should not be denied the opportunity of receiving these benefits.

The cottage colony of the Colfax School for the Tuberculous provides accommodations for patients who have not only all the advantages of the sanatorium regime and supervision but at the same time have the benefit of home cooking and surroundings. While the patient improves the other members of the family daily receive instructions relative to those things everyone should know regarding tuberculosis.

Information regarding the methods of treatment and other details of interest to the physician and his patient are given in a booklet which will be sent on request.

A Bloodless Field is promptly produced by the application or hypodermatic injection of

Suprarenalin Solution, 1:1000

—the stable and non-irritating preparation of the Suprarenal active principle. The e. e. n. and t. men find it the premier product of the kind.

Ischemia follows promptly the use of 1:10000 *Suprarenalin Solution* slightly warmed (make 1:10000 solution by adding 1 part of Suprarenalin Solution to 9 parts of sterile normal salt solution).

In obstetrical and surgical work *Pituitary Liquid* (Armour), physiologically standardized, gives good results—½ c. c. ampoules obstetrical—1 c. c. ampoules surgical. Either may be used in emergency.

Elixir of Enzymes is a potent and palatable preparation of the ferments active in acid environment—an aid to digestion, corrective of minor alimentary disorders and a fine vehicle for iodides, bromides, salicylates, etc.

As headquarters for the organotherapeutic agents, we offer a full line of Endocrine Products in powder and tablets (no combinations or shotgun cure-alls).

LABORATORY PRODUCTS

Armour's *Sterile Catgut Ligatures* are made from raw material selected in our abattoirs, plain and chromic, regular and emergency lengths, iodized, regular lengths, sizes 000—4.

THE CALIFORNIA STATE JOURNAL OF MEDICINE

Butler Bldg., 135 Stockton St., San Francisco, California Phone Douglas 62

Subscription prices, including postage, per annum in advance: Domestic, $4.00; Canadian, $5.00.

Domestic rates include United States, Cuba, Mexico, Hawaii, Guam, Porto Rico, Canal Zone and Philippine Islands.

Acceptance for mailing at special rate of postage provided for in Section 1103, Act of October 3, 1917, authorized August 10, 1918.

SINGLE COPIES of this calendar year, 50 cents.

REMITTANCES should be made by check, draft, registered letter, money or express order. **Currency should not be sent unless the letter is registered.** Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Medical Society, State of California."

VOLUMES begin with the first of January. Subscriptions may commence at any time.

CHANGE OF ADDRESS notice should give both the old and the new address, and state whether the change is permanent or temporary. The change notice must reach us ten days in advance of the date of the issue which is to be forwarded to the new address.

WARNING: Pay no money to an agent unless he presents a letter showing authority for making collection.

ADVERTISEMENTS.

Advertising forms go to press fifteen days in advance of the date of issue. In sending in copy time must be allowed for setting up advertisements and for sending proofs. No proprietary medicines can be advertised until approved by the Council on Pharmacy and Chemistry. Advertising rates will be sent on request.

CONTRIBUTIONS.

EXCLUSIVE PUBLICATION: Articles are accepted for publication on condition that they are contributed solely to this journal.

CONTRIBUTIONS TYPEWRITTEN: Authors must have their contributions typewritten—double-spaced and with ample margins—before submitting them. The expense is small to the author—the satisfaction is great to the editor and printer. We cannot promise to return unused manuscript, but try to do so in every instance. **Manuscript should not be rolled.**

ILLUSTRATIONS: Half-tones and zinc etchings, if necessary to elucidate the text, will be furnished by The Journal when satisfactory photographs or drawings are supplied by the author. Each illustration, table, etc., should bear the author's name on the back. Photographs should be clear and distinct; drawings should be made in black ink on white paper. While we cannot guarantee to return used photographs and drawings, we use our best endeavors to do so after the article is published, if the word "return" is written on the back of each.

ANONYMOUS CONTRIBUTIONS, whether for publication, for information, or in the way of criticism, are consigned to the wastebasket unread.

NEWS: Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to physicians. We shall be glad to know the name of the sender in every instance.

MORE people die from pneumonia than any other disease.

Approximately 25 out of every 100 cases end fatally. Dr. Gustav Goldman has demonstrated that at least twenty of these twenty-five deaths may be prevented by employing Bacterial Vaccines.

Why delay and chance a fatal termination?

Dr. Gustav Goldman's article appeared in American Medicine, March, 1921

Bacteriological Laboratories of
G. H. SHERMAN, M. D.
DETROIT, U. S. A.

PNEUMOCOCCUS ANTIGEN

PARTIALLY AUTOLYZED PNEUMOCOCCI

FOR THE TREATMENT OF PNEUMONIA

Prepared according to the method of Dr. E. C. Rosenow,
now of the Mayo Foundation, Rochester, Minnesota

A polyvalent antigen for subcutaneous use in the treatment of primary infections due to pneumococci of the various types with resulting clinical pneumonia.

The distinctly favorable impressions reported by many physicians and the constantly increasing demand for the product support the belief that in Pneumococcus Antigen is to be had a measure of able assistance in combating pneumococcus infections. Supplied only in 5 c.c. rubber-capped vials (20 billion partially autolyzed pneumococci in each c.c.).

ELI LILLY & COMPANY

INDIANAPOLIS, U. S. A.

6 POINTS TO REMEMBER WHEN CHOOSING MEAD'S DEXTRI-MALTOSE TO MODIFY COW'S MILK FOR BOTTLE BABIES. ∴ ∴

POINT NO. 1

It does not have directions on the package, as these interfere with the doctor's instructions to mothers.

POINT NO. 2

It is not advertised in the women's magazines and other lay papers, as this is unethical.

POINT NO. 3

Literature on infant feeding is not mailed to mothers.

MEAD'S DEXTRI-MALTOSE

(Dextrins and Maltose)

Has been used by thousands of physicians for over 10 years because it gives gratifying results in infant feeding and because it is a strictly ethical product.

A Three Way Winner

10 days' trial will prove its value to the doctor, the mother and the infant.

THE MEAD JOHNSON POLICY

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information regarding their use reaches the mother only by written instructions from her doctor on his private prescription blank. Literature furnished only to physicians.

POINT NO. 4

It contains the proper food salts. Sodium Chloride for average babies, Potassium Bicarbonate for constipated babies.

POINT NO. 5

It contains no protein, cellulose or fat. It is used as a malt sugar and a sugar it should be.

POINT NO. 6

It contains Dextrins 43%, Maltose 52%, Moisture 5%. These proportions were selected by Pediatricians.

Samples and Literature Furnished on Request

MEAD JOHNSON & COMPANY EVANSVILLE, INDIANA

Dr. King's Sanatorium

(THE BANNING SANATORIUM)

Banning (Riverside County) California

This well known institution (for the treatment of tuberculosis of the throat and chest) has recently been rebuilt and enlarged. The City of Banning (suffering from phthisiophobia) passed a "zoning" ordinance that forced abandonment of the former site of this sanatorium. A new site was purchased. An injunction was sought to prevent the use of the new site for sanatorium purposes. A temporary injunction was granted but, at the final hearing, this injunction was dissolved and the right to build and maintain the sanatorium was established. Many of the most prominent physicians in the state contributed testimony that enabled us to win the suit. During the progress of these suits the institution found it difficult to provide for patients demanding admission. Now, however, in its new quarters, it is prepared to accept all who apply. To physicians who are unfamiliar with our work we will gladly furnish references to other physicians (in almost every town in California) who have had patients or relatives in this institution. A circular describing conditions and containing rates will be mailed upon request. Address

DRS. KING and BRAMKAMP. BANNING, CALIFORNIA.

HAY FEVER MEMORANDA

EARLY SPRING TYPE. Patients whose hay fever develops in late March, April, or beginning of May, should be tested with pollens of early flowering trees as: Poplar, birch, maple, willow, walnut, oak, which pollinate in the order named.

LATE SPRING TYPE. Patients whose hay fever develops in the latter part of May, during June or early July, should be tested with the pollens of sweet vernal grass, June grass, orchard grass, timothy and red top. The one giving the major reaction should be selected for treatment to the group. The unrelated rose pollinates simultaneously and is the primary or secondary cause in an occasional cause—hence should be included in tests where direct exposure exists. The same is true of dandelion, daisy and, in some sections, alfalfa.

ARLCO—POLLEN EXTRACTS

For **Cutaneous Tests** and **Treatment** cover early and late spring, also **summer** and autumn.

A THOROUGHLY EQUIPPED INSTITUTION affording unexcelled facilities for the scientific administration of Radium Therapy and the study and treatment of Neoplastic diseases.

THE NEW AND MODERN FIREPROOF BUILDING contains private rooms for bed and ambulatory cases, completely equipped examination and treatment rooms, Roentgen Ray, clinical and research laboratories.

THE RADIUM LABORATORY, in addition to a large and adequate quantity of Radium, is equipped with a Duane emanation apparatus and all necessary appliances, affording the most modern and complete facilities for Radium Therapy.

THIS INSTITUTION, substantially endowed, is in its equipment and capacity equal to any other in this country, and is the largest and most complete in the United States, devoted exclusively to this work.

WE DESIRE TO CONFER and cooperate with the medical profession regarding the use of Radium in appropriate cases.

THE BABY CLARKE is appropriately named. It is a portable gas outfit which the physician can very well take with him as part of his obstetrical equipment. There is constant and legitimate call from women patients that some of the terrors of obstetrical pain be relieved. It is the common practice now in hospitals to use gas for this purpose. THE BABY CLARKE will render the same service to the obstetrician and may be carried to the patient's home and used there or anywhere else.

The portable apparatus is automatic, and requires no attention in analgesia, also used in minor operations. Most progressive men are using Nitrous Oxid-Oxygen in their Obstetrics.

DOES NOT DISTURB THE PATIENT

Made in two parts, simply, yet strongly connected, the Gwin-Flex stretcher can be readily removed without disturbing the patient. In many post-operative conditions the use of this stretcher insures not only greater comfort for the patient, but likewise far greater safety.

The two parts of the Gwin-Flex Stretcher are held together by a flexible steel tape which is easily removed, enabling both parts of the stretcher to be withdrawn without disturbing the patient. The stretcher is readily sterilized as the handles and tape are removable. The stretcher is extremely strong, although light in weight. Particularly convenient in turning sharp angles and passing through doorways.

May we send you full particulars, together with list of prominent hospitals now using the Gwin-Flex Stretcher?

For those patients demanding the use of Radium and X-Ray we are in a position to offer to the medical profession the full and unqualified services of our laboratory. This laboratory is equipped with both Radium element and a complete Emanation plant which enables us to construct any application we may desire to fit the given case. To those physicians wishing to make their own application we are prepared to serve with Radium emanation as they may direct.

Address Dr. D. H. Trowbridge,
Secretary Burnett Sanitarium Co.

CALCREOSE

"CREOSOTE and * * * * are used internally as intestinal and urinary antiseptics, as stimulant expectorants and in the treatment of tuberculosis. Their local irritant actions often interfere with their internal administration." (New and Non-official Remedies, 1921, p. 89.)

CALCREOSE is a mixture containing in loose chemical combination approximately equal weights of creosote and lime (calcium creosotate.)

CALCREOSE administered internally has the same actions and uses as creosote, but does not readily produce gastric distress, nausea and vomiting even when large quantities are taken for comparatively long periods of time.

CALCREOSE may be given in the form of solution or tablets.

THE KROMAYER LAMP

Consider—

that the Kromayer lamp enjoys the distinction for highest intensity of Ultra-Violet radiation and the most practical means for administering treatment of many conditions.

The effective results obtained with its use over a period of ten years has been the stimulant for our scientific research work that has resulted in bringing the lamp to its present high state of efficiency.

It is chosen as the most desirable method of applying actinic rays to Lupus, Naevus, Acne, Psoriasis, Eczema, Ulcers and Wounds; to specific or non-specific orificial inflammatory conditions such as Tubercular Laryngitis, Rectal Fistulae, Otitis Media, Frontal Sinus Infections, Ozena and a number of gynecological conditions.

MADE IN THE GOOD OLD U. S. A.

A Thoroughly Soft, Pliable, Transparent

DRESSING MATERIAL

Cellosilk is a product developed by American Science to meet the long felt need of the medical profession for a suitable dressing of this kind. It is prepared from Cotton, Gums, and carefully blended, is suitable for all dressing purposes.

PERFORATED AND IMPERVIOUS FORMS

Impervious Cellosilk is used as a protective covering over all wet and moist dressings, as a direct Impervious dressing where such is indicated, and for drains.

Perforated Cellosilk is used as a direct, non-adherent dressing for all granulating wounds; burns, skin grafts, ulcers, mastoid operations, etc.

Secure Cellosilk from your regular supply house. Both Perforated and Impervious forms should be on hand at all times for use as needed.

Marshalltown Laboratories, Inc. **Marshalltown, Iowa.**

NO EXHIBITS AT THE STATE MEETING

The Council and Publicity Bureau have decided that there will be no exhibits at the Yosemite meeting. Advertisers in the Journal may have accredited representatives at the meeting by making application to the State Secretary. This privilege will be limited to the advertisers who utilize the advertising pages of the State Journal.

Introducing

VITA RICE MILK

To the Medical Profession

Write for particulars

The study of rice culture, and patient experiments by dairy and food experts, have revealed this truth:

THE RICE KERNEL ENTIRE CONTAINS THE PERFECT FLUID FOOD FOR THE MOST DELICATE DIGESTIONS

Cream, with no refuse matter, extracted from the elements by the water roots or milk veins of the Rice plant.
Liquified and sterilized by the newly discovered natural process, and delivered in all its first purity, is VITA RICE MILK.

VITA RICE PRODUCTS CO.

407 FLATIRON BLDG. *SAN FRANCISCO*

We carry in stock a full line of standard Anti-toxins, Serums, Vaccines, Hypodermic Syringes and Needles. Neo-salvarsan and other preparations used hypodermatically and intravenously.

DOCTORS' SURGICAL FURNITURE SET

Only $154.75

15 DAYS FREE INSPECTION —— 6 MONTHS TO PAY —— SMALL PAYMENT DOWN

Just what you have been waiting for. Improves your technique, saves you time, increases your office efficiency. At this price you can afford to discard your obsolete office furniture and install new, white enameled, steel equipment.

Think of it! For only $154.75 you can secure this fine doctor's office furniture consisting of Patient's Chair, Four-Shelf Glass Front Instrument Cabinet, Instrument and Dressing Stand, Two-Basin Adjustable Irrigator, Operating Stool, Combination Operating, Examining and Treatment Table which is adjustable to any position, and One Waste Receptacle. And you can pay for it while using, if you like.

PURCHASED PIECE BY PIECE IT WOULD COST YOU $205

This is first grade merchandise. Not one whit less care or material has gone into this set than into any of our merchandise. Each piece is made of hand-rubbed, oven-baked, snow white enamel, and has been manufactured of the same high grade material which has made our hospital and surgical furniture world famous. No pains have been spared to make this set the finest the market affords.

You don't have to take our word for it. You will be taking no risk—we ship the set to you on approval. You set it up in your office, use it for 15 days, and if it proves unsatisfactory in any way, if it is not the best surgical furniture buy you ever made, if it does not improve your office, or if its construction does not suit, you may ship it back to us. We will stand the freight charges both ways, and the transaction will not cost you a penny.

There are only a limited number of these sets to sell at this introductory price. You must act quickly to get one of them. Remember, you take no risk—you inspect the set before you purchase. Don't delay—send us $38.69 as deposit—then after 15 days' inspection if you wish to pay cash send $112.98, which includes cash discount of $3.09, or if you wish to purchase on installments pay us $19.35 per month for 6 months—total $116.10.

Waterproof cushion for operating table, $6.00 extra. Prices F. O. B. our factory, Seattle, Wash. Set weighs 500 pounds, crated for shipment.

Gonorrheal Infections

INVOLVING deep-seated tissues, especially arthritis (gonorrheal rheumatism), prostatitis, epididymitis and posterior urethritis are conditions in which

Glycerol-Vaccine

Gonococcus

Lederle

affords encouraging results

Note: The Glycerol-Vaccines were introduced by the LEDERLE ANTITOXIN LABORATORIES early in 1920 and have since given uniformly consistent results of a satisfactory nature.

Advantages

It will not deteriorate. It is free from autolytic products.

Large doses can be tolerated without systemic reaction.

Marked improvement in arthritis cases after the first four or five doses.

Gonococci rapidly disappear from the urethral discharges.

Administration

Glycerol-Vaccine

Gonococcus

Lederle

is supplied in 15 concentrated serially numbered graduated doses.

Each dose is accompanied by a vial of sterile diluent with which dilution is made immediately before hypodermic administration, thus ensuring the potency of the vaccine.

WHOOPING-COUGH *causes more deaths*

under one year of age than any other infectious disease. In America more than 10,000 children die each year of whooping-cough

Glycerol-Vaccine

Pertussis

Lederle

is of value for the prevention and treatment of whooping-cough. The average duration of the disease under vaccine treatment is about 3½ weeks, while under other forms of treatment the average duration is from 9 to 12 weeks.

MILLER states (American Journal of Public Health, October, 1921):

"Whooping-cough vaccine is the only therapeutic measure worthy of consideration in the treatment of this disease. * * *

"I believe that public health authorities are justified in promoting immunization against whooping cough just as they are urging immunization against typhoid fever."

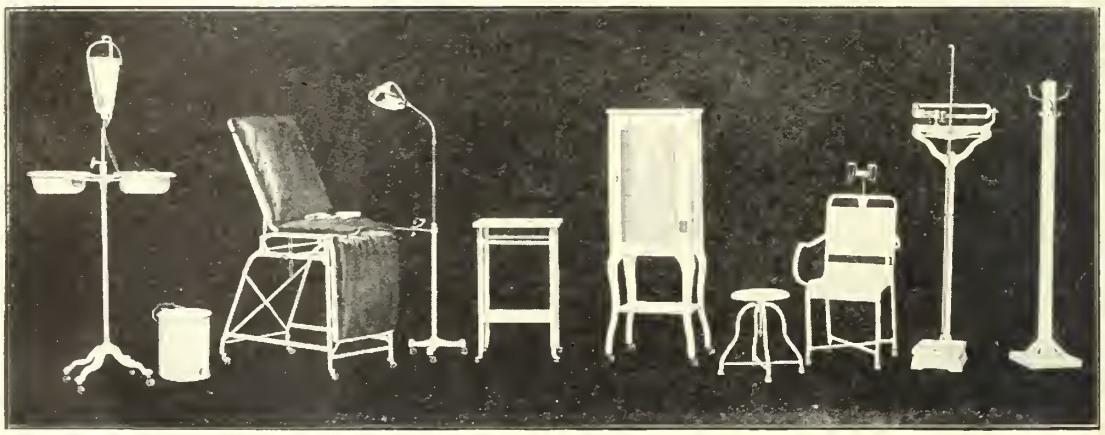
HERE IS COMPLETENESS

FOR GENERAL OFFICE PRACTICE

Ten Pieces of Snow-White Furniture

WITH SPECIAL OPERATING TABLE

Made with True Betzco Thoroughness



$50.00 Down—Easy Monthly Terms—Total $200.00

Betzco Eleven Piece General Practice Outfit has been created to meet the demand for an adequate outfit for physical examination, diagnosis, treatment and operations. It is one of the most complete and most reasonable outfits of its kind on the market. Behind it is our absolute guarantee of satisfaction or your money back. It offers every convenience for a successful and remunerative office practice. Nowhere will you find such an outfit at such a price—think of it—eleven pieces of the most modern equipment for $200.00. Every piece in the outfit is thoroughly practical, up to date and remarkably sturdy. There is no finer finish than the Betzco snow-white, wear-resisting enamel that is baked onto every piece of this furniture. Master workmen cut the steel, bend it, weld it and enamel it. Every detail of construction and finishing receives the most painstaking attention. The quality rings true because all processes of manufacture are careful and exact.

THIS OUTFIT INCLUDES

Folding Chair Table—Offers practically all positions required in office practice and folds flat for easy transportation. Equipped with large easy-roll casters, leg holders and heel stirrups.

Operating Cushion—Extra heavy, good leatherette covering, thick and comfortable.

Standard Model Intrument Cabinet—A modern, sanitary cabinet with four plate glass shelves, glass door and sides. Clean constructed from heavy, selected furniture steel, electric and torch welded. Height, 58 inches; width, 20 inches; depth, 15 inches. Mounted on easy-roll steel casters.

Platform Beam Scale—Has compound beam and telescoping measuring rod giving height from 2 ft. 6 in. to 6 ft. 6 in. Scale capacity 300 lbs. Inlaid rubber mat on platform.

Solution and Irrigator Stand—Provided with two revolving enameled immersion bowls in bracket and adjustable in height. Also equipped with complete irrigating outfit including bailed percolator, tubing, cut-off and rubber tips, adjustable in height. Mounted on easy-roll steel casters.

Specialist's Examining Chair—With headrest adjustable in height and mounted on rubber feet. Constructed with tubular wrought iron frame and heavy furniture steel, seat and back.

Operator's Adjustable Stool—A sturdy stool with revolving seat and mounted on rubber feet, adjustable from 18 to 24 inches.

Acid-Proof Utility Table—Acid-proof porcelain top, heavy pressed steel frame. Size 16 x 20, mounted on rubber feet.

All Steel Costumer—A convenient piece of furniture for the examining or reception room. Equipped with four large and four small brass hooks.

Adjustable Gooseneck Lamp—An indispensable convenience for examination and diagnosis. Has telescoping stand mounted on easy-roll steel casters. Readily adjustable to height or position.

Sanitary Waste Bucket—Has tight fitting cover which works automatically from foot pedal. Supplied with removable, galvanized container, bailed. Capacity, 16 qts.

SPECIAL TERMS Our special terms for this superb outfit are $50 with your order and $15 per month for 10 months. A real opportunity to secure complete and up-to-date equipment on the easiest terms.

Blood Counts on Blood Sent to the Laboratory

The value of a complete blood count as an aid in the diagnosis and prognosis of certain blood and other diseases is so well established that little need be said on that subject. What should interest all practitioners is the recent development of a new method of making complete blood counts on blood specimens sent to the laboratory. Heretofore it has been impractical for various reasons to have a blood count made in some cases because the patient's blood could not be sent to the laboratory for such examination. It was always necessary either to send the patient to the laboratory or to have the laboratory man call on the patient, but this is not always possible. No patient need now be deprived of the benefit of a complete blood count, because the laboratory can now make such counts on the blood taken by the physician and sent to the laboratory by mail or messenger.

The new method, in brief, is to collect a few c.c. of the patient's blood in a vial containing a few crystals of Potassium Oxalate. The technique for collecting the blood is the same as that used for collecting specimen for the Wassermann test. After collecting the blood the vial is shaken for one minute to dissolve the Potassium Oxalate, which prevents the blood from clotting. The specimen is then sent to the laboratory for examination.

Comparison of the counts made on blood obtained by this new method with counts made in the usual way, on the same patient, shows practically identical results. Blood collected by this new method will keep at least three days and give correct counts. Of course, where it is practical for the laboratory to collect the specimen by the usual method, that would be the method of choice.

Every physician should have one of these special containers in his emergency bag, ready to collect the patient's blood in this simple manner to be forwarded to the laboratory. Just write or telephone us and we will be glad to send you a supply of these containers.

COMPLETE BLOOD COUNT, $5.00

(Including red, white, and differential counts, hemoglobin, malaria and morphology of red cells)

The Management of an Infant's Diet

Constipation

Constipation in infancy is a symptom that should not be passed over lightly, for deferred elimination of the waste products of digestion, especially if allowed to become chronic, may lead to digestive disorders difficult to correct. Loss of appetite, disturbed sleep, a slow gain in weight and a generally uncomfortable baby are some of the early signs that are likely to be observed, as well as a change in the consistency of the infant's previously normal stool.

The Mellin's Food Method of Milk Modification

offers a very good opportunity to accomplish much toward the relief of infantile constipation, for by the employment of this method the physician may study the effect of different food elements upon the individual infant and draw a satisfactory conclusion as to the real cause of delayed bowel movements. In the chapter on "Stools" in our book, "Formulas for Infant Feeding," and in a pamphlet devoted particularly to this subject, practical suggestions are made that will be found of material assistance, and this literature will be sent to any physician upon request.

COTTAGE DEPARTMENT

THE LIVERMORE SANITARIUM

HYDROPATHIC DEPARTMENT

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the U. S.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) $45.00 per week and upward.

SERVICE RENDERED ONLY TO PATIENTS REFERRED TO US BY THE MEDICAL PROFESSION. NO OTHER CASES ACCEPTED

We are well equipped with modern mechanical devices of scientifically proven efficiency for the *Relief* of *Suffering.* We maintain a most comprehensive *Service Organization* of *Trained Attendants* rendering *Personalized Attention* to every patient.

The following chronic indications are most successfully treated at this Institute: *General Debility; Protracted Convalescence; Disorders of Nutrition* and the *Alimentary Tract; Cardio-Vascular* and *Renal Disorders; Functional Disturbances* of the *Nervous System; Ankylosed Joints; Muscle Atrophy; Defects* of *Physical Development.*

DOCTOR — The Physicians Institute endeavors to meet a great and necessary co-operative role with the Physicians and Surgeons of San Francisco and Bay Cities, in their fight with intractable morbid conditions. Our Institute is simply a unique and efficient therapeutic agent, available to all reputable physicians who want to retain their patients, but desire to place them in the hands of specially trained technicians who are equipped with the required modern therapeutic appliances and experience, and who make a specialty of coping with conditions described.

WHY NOT INVESTIGATE THOROUGHLY ABOUT US TODAY?

X-RAY APPARATUS SIMPLIFIED

WHEN the first cameras were introduced, over half a century ago, only a few photographers could use them. The modern camera, more complicated than any camera of the old days, is in the hands of many.

So it is with X-Ray apparatus. It was simpler in its earlier forms, but only a few men could use it—men who were not only physicians but physicists and electricians. In its modern form the Victor X-Ray machine no longer presents mysteries that the physician cannot master.

Two policies of the Victor X-Ray Corporation have made it possible thus to extend the use of X-Ray machines.

The one is the policy of conducting research persistently and systematically, so that the machine has become more and more automatic in character. The other is the policy of establishing Service Stations to which physicians can turn if their machines need attention or if they need guidance in obtaining the best results.

Because it is not an ordinary commercial organization, engaged solely in selling apparatus useful to physicians, but rather a scientific institution dedicated to the advancement of X-Ray technique, the Victor X-Ray Corporation does not usually sell its apparatus without first satisfying itself that it will meet a physician's requirements. A technically trained representative is sent, on request, from one of its Service Stations to make a study of a physician's needs. Not until then is any special type of Victor apparatus recommended.

NOTICE—The Executor of the last will of the late Dr. W. S. Hickman (Dr. Hickman in his lifetime was engaged in the general practice of medicine at the village of Georgetown in the County of El Dorado, California, since about 1886 until about some six months ago) wishes to dispose of to some physician and surgeon the library (a small one), surgical instruments and other office and practitioner supplies, and wishes likewise to dispose of the house and lot formerly used as a residence and office. Since Dr. Hickman's death there has been no resident physician there and the nearest practicing physicians are at Placerville, Auburn and Folsom. For further particulars address George H. Thompson, Executor, etc., Placerville, El Dorado County, Calif.

INFLUENZA is reported to be prevalent in many sections of the country.

With many physicians the first thought on approach of an epidemic of colds, sore throat, and so-called "grippe" is the selection of an efficient Antiseptic as a spray or gargle.

CHLORAZENE

is fast becoming the universal antiseptic.

AROMATIC CHLORAZENE POWDER
Is an efficient and pleasing antiseptic gargle

IODALBIN

a protein-iodine compound for internal administration

THE therapeutic effects for which you prescribe iodides are produced most readily by those iodine compounds that are easily split up in the body. It is the available iodine that does the work.

In the case of Iodalbin, contact with the intestinal juice severs the loose bonds that unite the iodine with the protein base.

That's what makes Iodalbin rapidly effective.

And besides being effective, its blandness makes it acceptable to sensitive patients. It is especially gratifying to those who object to the taste and nauseating effect of sodium or potassium iodide.

A fair average dose for such cases as pleuritic effusion, dry bronchitis, lead poisoning, chronic rheumatic arthritis and the minor degrees of hypothyroidism, is 5 grains, repeated three or four times a day. Even in certain other diseases—cases requiring much larger doses, such as tertiary syphilis and myxedema—Iodalbin can be given with a minimum of discomfort to the patient.

Parke, Davis & Company

Supplied as a powder in ounce vials and in 5-grain capsules.

OVALTINE

In Pregnancy and Lactation

There are many reasons for the widespread use of "Ovaltine" in the diet of maternity. Physicians the world over recognize its value not only as an effective means of promoting the flow and quality of the milk of the nursing mother but as a form of nutriment ideally adapted to prenatal requirements.

"Ovaltine" has a marked galactagogue action attributed to its richness in maltose and other food principles having specific galactagogue qualities and also to the fact that these principles are almost completely absorbed with minimum digestive disturbance. The use of "Ovaltine," commenced during the later stages of gestation and continued throughout the nursing period, materially aids in promoting the general health of the mother enabling her to withstand the extra strain imposed upon the system.

For similar reasons "Ovaltine" is a valuable adjunct to the diet during the whole period of pregnancy. It counteracts any tendency to constipation, and in cases of vomiting, clinical experience has shown that it is well retained when ordinary forms of nourishment are rejected by the patient.

"Ovaltine" is taken as a delicious beverage which can be prepared at a moment's notice without bother, mess or trouble of any kind.

Samples and literature mailed to physicians upon signed request.

Supplied by druggists at 50c, 80c, $1.50 and $5.00.

YOSEMITE

Once upon a time there settled in California two young school teachers who had long wished to see the Yosemite Valley but found that it was inaccessible to their pocketbooks.

They started a vacation-time camp there for people in the same frame of mind. That was in 1899. They had seven tents, they had the choicest spot in all Yosemite for their camping ground, and they had faith and energy and a vital spirit of hospitality.

Today over 600 tents and thirty-odd bungalows cluster about a central group of buildings with a dining room seating 800 comfortably, a spacious auditorium with a capital dancing floor, a picturesque studio and soda fountain, offices, bath houses and laundry, an open air swimming tank, and the finest electrical cooking and water heating system in the country.

These are the incidentals of progress. The big thing is that the years have justified the faith of Mr. and Mrs. Curry that people wish to see Yosemite—not just the wealthy tourist and the "globe trotter," but the people of California and the people of the United States.

In nearly a quarter of a century under the personal management of its owners, 150,000 visitors have seen Yosemite through Camp Curry service.

This **personal management** means that Camp Curry is not a machine but a living organism, responsive to action and reaction.

—That throughout the camp, in tent or bungalow, in the dining room, around the camp fire, there are people who are directly interested in making you at home, in looking out for your comfort and enjoyment.

—That you and your fellow guests are all one great family, sharing a common purpose, enjoying your own possessions, all of you lovers of Yosemite.

Above all it means that the spirit of the place is still the faith in which it was started—and that Mrs. Curry is still the gracious hostess and the moving spirit of Camp Curry.

FOR A GOOD TIME GO TO

American Plan—$4.00 per day in tents; $6.00 per day in bungalows with bath or shower.

THYROXIN

Prepared only by E. R. SQUIBB & SONS

Under License of the

University of Minnesota

PURE, crystalline Thyroxin is the physiologically active constituent of the thyroid gland; a compound of definite and known chemical composition containing 65 per cent. of iodine, organically combined, as an integral part of the molecule.

Fifteen grains of desiccated thyroid prepared under favorable conditions contains approximately 1/64 grain of Thyroxin. This ratio may be used in determining the initial dose of Thyroxin.

The physiological action of Thyroxin bears a quantitative relation to the production of body energy, and a system that is lacking in such energy may be brought up to normal production by its administration.

Thyroxin is marketed in two forms—Tablets containing the partially purified sodium salt of Thyroxin for oral administration; and the Pure Crystalline Thyroxin for intravenous injection in those cases in which the Thyroxin is not absorbed quantitatively when given by mouth.

Complete Information on Request.

Colfax School for the Tuberculous

Experience has shown that Sanatorium treatment is the most efficient and most approved method of treating the tuberculous. Those patients who are able to take advantage of the superior facilities offered by sanatorium treatment should not be denied the opportunity of receiving these benefits.

The cottage colony of the Colfax School for the Tuberculous provides accommodations for patients who have not only all the advantages of the sanatorium regime and supervision but at the same time have the benefit of home cooking and surroundings. While the patient improves the other members of the family daily receive instructions relative to those things everyone should know regarding tuberculosis.

Information regarding the methods of treatment and other details of interest to the physician and his patient are given in a booklet which will be sent on request.

The Endocrines, Digestive Ferments, Catgut Ligatures, etc.

THE ARMOUR LABORATORY is maintained for the purpose of handling the glands, membranes and other raw materials supplied by our abattoirs in immense quantities, from which important therapeutic agents are extracted and fabricated.

Among the products that the physicians and surgeons use daily are:

Corpus Luteum; Suprarenals, U.S.P.; Parathyroids; Pituitary, Whole Gland; Pituitary, Anterior; Pituitary, Posterior and other glandular substances in po. and tabs. Pituitary Liquid in 1 c. c. and 1-2 c. c. ampoules.

Armour's LABORATORY PRODUCTS

Suprarenalin Solution 1:1000; Suprarenalin Ointment 1:1000; Pepsin, U. S. P.; Pancreatin, U. S. P.; and other preparations of the Digestive Ferments that are used in stomachic and intestinal disorders and as vehicles for nauseating drugs.

We also make Sterile Surgical Catgut Ligatures, plain and chromic, boilable; and Iodized Ligatures, non-boilable. ¶ The Armour ligatures are made from Lamb's gut, selected especially for surgical purposes and sterilized at opportune stages in such manner as to preclude the possibility of contamination in the finished strings.

We are headquarters for the Organotherapeutic Agents and are always glad to co-operate with the medical profession

THAT physicians may examine medical books at their leisure, and uninterrupted, we have opened a special medical department adjacent to the Book Department at the rear of the first floor.

* *

In appreciation of the faithful patronage of so many of our most prominent physicians we have enlarged our medical book department with the aim of making its service the best in the United States.

* *

A cordial welcome is extended to visiting physicians to make it their downtown headquarters.

THE CALIFORNIA STATE JOURNAL OF MEDICINE

Butler Bldg., 135 Stockton St., San Francisco, California Phone Douglas 62

Subscription prices, including postage, per annum in advance: Domestic, $4.00; Canadian, $5.00.

Domestic rates include United States, Cuba, Mexico, Hawaii, Guam, Porto Rico, Canal Zone and Philippine Islands.

Acceptance for mailing at special rate of postage provided for in Section 1103, Act of October 3, 1917, authorized August 10, 1918.

SINGLE COPIES of this calendar year, 50 cents.

REMITTANCES should be made by check, draft, registered letter, money or express order. **Currency should not be sent unless the letter is registered.** Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Medical Society, State of California."

VOLUMES begin with the first of January. Subscriptions may commence at any time.

CHANGE OF ADDRESS notice should give both the old and the new address, and state whether the change is permanent or temporary. The change notice must reach us ten days in advance of the date of the issue which is to be forwarded to the new address.

WARNING: Pay no money to an agent unless he presents a letter showing authority for making collection.

ADVERTISEMENTS.

Advertising forms go to press fifteen days in advance of the date of issue. In sending in copy time must be allowed for setting up advertisements and for sending proofs. No proprietary medicines can be advertised until approved by the Council on Pharmacy and Chemistry. Advertising rates will be sent on request.

CONTRIBUTIONS.

EXCLUSIVE PUBLICATION: Articles are accepted for publication on condition that they are contributed solely to this journal.

CONTRIBUTIONS TYPEWRITTEN: Authors must have their contributions typewritten—double-spaced and with ample margins—before submitting them. The expense is small to the author—the satisfaction is great to the editor and printer. We cannot promise to return unused manuscript, but try to do so in every instance. **Manuscript should not be rolled.**

ILLUSTRATIONS: Half-tones and zinc etchings, if necessary to elucidate the text, will be furnished by The Journal when satisfactory photographs or drawings are supplied by the author. Each illustration, table, etc., should bear the author's name on the back. Photographs should be clear and distinct; drawings should be made in black ink on white paper. While we cannot guarantee to return used photographs and drawings, we use our best endeavors to do so after the article is published, if the word "return" is written on the back of each.

ANONYMOUS CONTRIBUTIONS, whether for publication, for information, or in the way of criticism, are consigned to the wastebasket unread.

NEWS: Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to physicians. We shall be glad to know the name of the sender in every instance.

ANNOUNCES

THAT ITS X-RAY DEPARTMENT IS NOW EQUIPPED

WITH A

MODERN DEEP THERAPY X-RAY APPARATUS

FOR THE

PRE- AND POST-OPERATIVE RADIATION OF DEEP MALIGNANCY

AND THE

TREATMENT OF INOPERABLE MALIGNANT CONDITIONS

This type of apparatus with its ability to produce a voltage of 280,000 volts (about twice the voltage capacity of X-ray machines hitherto available) gives an X-ray beam of enormously magnified penetrating power as compared to those previously in use.

Heavy filtration is used as an added factor in increasing the ratio of the depth to the skin dose, thus markedly decreasing the liability of injurious skin effects while as markedly increasing the effect on the deep tissues.

MEAD'S

MEAD'S DEXTRI-MALTOSE

(Dextrins and Maltose)

For Infant Feeding

A PHYSICIANS' PRODUCT BACKED BY "SERVICE THAT SERVES"

MEAD'S DEXTRI-MALTOSE comes in a full pound (16 ounce) package. The day of prescribing infant diet materials by the CAN, by the BOTTLE, or by the BAG has passed. Pounds and ounces mean dollars and cents to the mother. She knows that twelve ounces are not a pound but only three-quarters of a pound. The combination of MEAD'S DEXTRI-MALTOSE, Fresh Cow's Milk and Water gives gratifying results in infant feeding.

MEAD'S represents MORE for LESS instead of LESS for MORE

THE MEAD JOHNSON POLICY

Mead's infant diet materials are advertised only to physicians. No feeding directions accompany trade packages. Information regarding their use reaches the mother only by written instructions from her doctor on his private prescription blank. Literature furnished only to physicians.

Literature and Samples on Request

City State C

Dr. King's Sanatorium

(THE BANNING SANATORIUM)

Banning (Riverside County) California

This well known institution (for the treatment of tuberculosis of the throat and chest) has recently been rebuilt and enlarged. The City of Banning (suffering from phthisiophobia) passed a "zoning" ordinance that forced abandonment of the former site of this sanatorium. A new site was purchased. An injunction was sought to prevent the use of the new site for sanatorium purposes. A temporary injunction was granted but, at the final hearing, this injunction was dissolved and the right to build and maintain the sanatorium was established. Many of the most prominent physicians in the state contributed testimony that enabled us to win the suit. During the progress of these suits the institution found it difficult to provide for patients demanding admission. Now, however, in its new quarters, it is prepared to accept all who apply. To physicians who are unfamiliar with our work we will gladly furnish references to other physicians (in almost every town in California) who have had patients or relatives in this institution. A circular describing conditions and containing rates will be mailed upon request. Address

DRS. KING and BRAMKAMP. BANNING, CALIFORNIA.

HAY FEVER MEMORANDA

EARLY SPRING TYPE. Patients whose hay fever develops in late March, April, or beginning of May, should be tested with pollens of early flowering trees as: Poplar, birch, maple, willow, walnut, oak, which pollinate in the order named.

LATE SPRING TYPE. Patients whose hay fever develops in the latter part of May, during June or early July, should be tested with the pollens of sweet vernal grass, June grass, orchard grass, timothy and red top. The one giving the major reaction should be selected for treatment to the group. The unrelated rose pollinates simultaneously and is the primary or secondary cause in an occasional cause—hence should be included in tests where direct exposure exists. The same is true of dandelion, daisy and, in some sections, alfalfa.

ARLCO—POLLEN EXTRACTS

THE BABY CLARKE is appropriately named. It is a portable gas outfit which the physician can very well take with him as part of his obstetrical equipment. There is constant and legitimate call from women patients that some of the terrors of obstetrical pain be relieved. It is the common practice now in hospitals to use gas for this purpose. THE BABY CLARKE will render the same service to the obstetrician and may be carried to the patient's home and used there or anywhere else.

The portable apparatus is automatic, and requires no attention in analgesia, also used in minor operations. Most progressive men are using Nitrous Oxid-Oxygen in their Obstetrics.

Diagnosis **Therapy**

X-Ray **Radium** **Laboratory**

Burnett Sanitarium

Fresno, California

For those patients demanding the use of Radium and X-Ray we are in a position to offer to the medical profession the full and unqualified services of our laboratory. This laboratory is equipped with both Radium element and a complete Emanation plant which enables us to construct any application we may desire to fit the given case. To those physicians wishing to make their own application we are prepared to serve with Radium emanation as they may direct.

Address Dr. D. H. Trowbridge,
Secretary Burnett Sanitarium Co.

CALCREOSE

"CREOSOTE and * * * * are used internally as intestinal and urinary antiseptics, as stimulant expectorants and in the treatment of tuberculosis. Their local irritant actions often interfere with their internal administration." (New and Non-official Remedies, 1921, p. 89.)

CALCREOSE is a mixture containing in loose chemical combination approximately equal weights of creosote and lime (calcium creosotate.)

CALCREOSE administered internally has the same actions and uses as creosote, but does not readily produce gastric distress, nausea and vomiting even when large quantities are taken for comparatively long periods of time.

CALCREOSE may be given in the form of solution or tablets.

Post-operative, maternity and hernia cases are especially well cared for in a unique and efficient manner. For twenty-one years we have made our business a study, and by confining ourselves to these specialties have developed methods that assure relief to the patient and satisfaction to the doctor.

Every physician should secure a copy of our catalogue, which explains our business in detail. We have the largest and best equipped plant on the Pacific Coast and are the exclusive agents for the famous Drs. Smith's "Honest John" Truss, the only practical device for holding at the internal ring.

Directory of Endorsed Advertisers

It is the purpose of the Journal to develop on this page a list of advertisers who wish to insert classified advertisements. The same censorship will be applied to these advertisements as is now used in the reading columns and other advertising columns of the Journal. The space will be limited to five lines and advertisements will all be uniform in size and type. Suitable headings or classifications will be arranged as required. No advertisements will be accepted for less than six months, and the rates are $2.00 per issue.

THE ALPINE SUN LAMP

THE Alpine Sun Lamp illustrated above presents the most convenient source of intense Ultra-Violet Light known at the present time.
Its field of indications covers Tuberculosis in most of its manifestations, superficial skin lesions, nervous diseases, post-operative infections, osteomyelitis, sluggish ulcers, and conditions resulting from faulty metabolism.

Standard

SINCE the advent of the Alpine Sun Lamp over a decade ago the high standard set for it has always been upheld.

Long researches by us and clinical tests made by users, have made this lamp an instrument of physical and mechanical precision, particularly typified by the model shown in the accompanying illustration.

And the consistent good work continues!

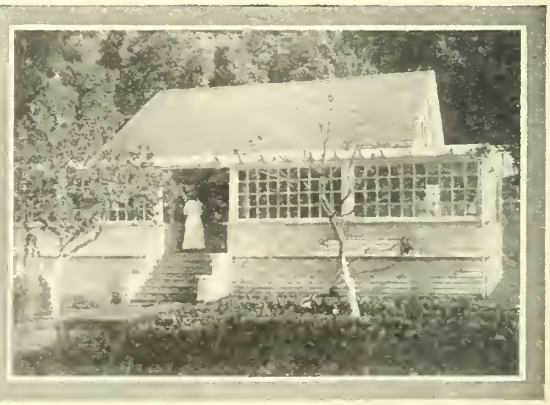
ALEXANDER SANATORIUM

BELMONT, CALIFORNIA

A Place for the Treatment of Nervous and Mild Mental Diseases



22 MILES FROM SAN FRANCISCO

Situated in the beautiful foothills of Belmont on Half Moon Bay Boulevard. The grounds consist of seven acres studded with live oaks and blooming shrubbery.
Rooms with or without baths, suite, sleeping porches and other home comforts as well as individual attention, and good nursing.

FINE CLIMATE YEAR AROUND

Best of food, most of which is grown in our garden, combined with a fine dairy and poultry plant. Excellent opportunity for outdoor recreation—wooded hillsides, trees and flowers the year around.

Just the place for the overworked, nervous, and convalescent. Number of patients limited. Physician in attendance.

ADDRESS

Phone Belmont 21 **ALEXANDER SANATORIUM** Box 27, BELMONT, CALIF.

MADE IN THE GOOD OLD U. S. A.

A Thoroughly Soft, Pliable, Transparent

DRESSING MATERIAL

Cellosilk is a product developed by American Science to meet the long felt need of the medical profession for a suitable dressing of this kind. It is prepared from Cotton, Gums, and carefully blended, is suitable for all dressing purposes.

PERFORATED AND IMPERVIOUS FORMS

Impervious Cellosilk is used as a protective covering over all wet and moist dressings, as a direct Impervious dressing where such is indicated, and for drains.

Perforated Cellosilk is used as a direct, non-adherent dressing for all granulating wounds; burns, skin grafts, ulcers, mastoid operations, etc.

Secure Cellosilk from your regular supply house. Both Perforated and Impervious forms should be on hand at all times for use as needed.

Marshalltown Laboratories, Inc. **Marshalltown, Iowa.**

MORE people die from pneumonia than any other disease.

Approximately 25 out of every 100 cases end fatally. Dr. Gustav Goldman has demonstrated that at least twenty of these twenty-five deaths may be prevented by employing Bacterial Vaccines.

Why delay and chance a fatal termination?

Dr. Gustav Goldman's article appeared in American Medicine, March, 1921

DOCTORS' SURGICAL FURNITURE SET

Only $154.75

15 DAYS FREE INSPECTION —— 6 MONTHS TO PAY —— SMALL PAYMENT DOWN

Just what you have been waiting for. Improves your technique, saves you time, increases your office efficiency. At this price you can afford to discard your obsolete office furniture and install new, white enameled, steel equipment.

Think of it! For only $154.75 you can secure this fine doctor's office furniture consisting of Patient's Chair, Four-Shelf Glass Front Instrument Cabinet, Instrument and Dressing Stand, Two-Basin Adjustable Irrigator, Operating Stool, Combination Operating, Examining and Treatment Table which is adjustable to any position, and One Waste Receptacle. And you can pay for it while using, if you like.

PURCHASED PIECE BY PIECE IT WOULD COST YOU $205

This is first grade merchandise. Not one whit less care or material has gone into this set than into any of our merchandise. Each piece is made of hand-rubbed, oven-baked, snow white enamel, and has been manufactured of the same high grade material which has made our hospital and surgical furniture world famous. No pains have been spared to make this set the finest the market affords.

You don't have to take our word for it. You will be taking no risk—we ship the set to you on approval. You set it up in your office, use it for 15 days, and if it proves unsatisfactory in any way, if it is not the best surgical furniture buy you ever made, if it does not improve your office, or if its construction does not suit, you may ship it back to us. We will stand the freight charges both ways, and the transaction will not cost you a penny.

There are only a limited number of these sets to sell at this introductory price. You must act quickly to get one of them. Remember, you take no risk—you inspect the set before you purchase. Don't delay—send us $38.69 as deposit—then after 15 days' inspection if you wish to pay cash send $112.98, which includes cash discount of $3.09, or if you wish to purchase on installments pay us $19.35 per month for 6 months—total $116.10.

Waterproof cushion for operating table, $6.00 extra. Prices F. O. B. our factory, Seattle, Wash. Set weighs 500 pounds, crated for shipment.

Gonorrheal Infections

INVOLVING deep-seated tissues, especially arthritis (gonorrheal rheumatism), prostatitis, epididymitis and posterior urethritis are conditions in which

Glycerol-Vaccine

Gonococcus

Lederle

affords encouraging results

Note: The Glycerol-Vaccines were introduced by the LEDERLE ANTITOXIN LABORATORIES early in 1920 and have since given uniformly consistent results of a satisfactory nature.

Advantages

It will not deteriorate. It is free from autolytic products.

Large doses can be tolerated without systemic reaction.

Marked improvement in arthritis cases after the first four or five doses.

Gonococci rapidly disappear from the urethral discharges.

Administration

Glycerol-Vaccine

Gonococcus

Lederle

is supplied in 15 concentrated serially numbered graduated doses.

Each dose is accompanied by a vial of sterile diluent with which dilution is made immediately before hypodermic administration, thus ensuring the potency of the vaccine.

WHOOPING-COUGH *causes more deaths*

under one year of age than any other infectious disease. In America more than 10,000 children die each year of whooping-cough

Glycerol-Vaccine

Pertussis

Lederle

is of value for the prevention and treatment of whooping-cough. The average duration of the disease under vaccine treatment is about 3½ weeks, while under other forms of treatment the average duration is from 9 to 12 weeks.

MILLER states (American Journal of Public Health, October, 1921):

"Whooping-cough vaccine is the only therapeutic measure worthy of consideration in the treatment of this disease. * * *

"I believe that public health authorities are justified in promoting immunization against whooping cough just as they are urging immunization against typhoid fever."

YOSEMITE

THE STORY HOUR AT CAMP CURRY'S KIDDIE KAMP

Yosemite is within 12 hours of San Francisco, 18 of Los Angeles. Leaving San Francisco by the Southern Pacific at 8:40 a. m. or 11:00 p. m. (Pullman to Merced), and by the Santa Fe at 9:00 a. m. or 4:00 p. m. (staying overnight in Merced), you will arrive at Camp Curry at 7:00 p. m. or at 1:00 p. m. Leaving Los Angeles on the Southern Pacific at 6:15 or 7:30 p. m. you will arrive at Camp Curry at 1:00 p. m.

Make a vacation of it and bring your family along to enjoy Yosemite with you. Our Kiddie Kamp will take care of the children. There are swings and a sand pile and games, and a charming woman to look after the children and entertain them.

Vigorous exercise if you wish it; rest and relaxation; and Yosemite in the spring of the year! Renew your youth as you wander about the Valley and take the mountain trails, or motor over the roads with their breath-taking vistas.

The Management of an Infant's Diet

Constipation

Protein indigestion or the failure to take care of the casein of cow's milk may result in delayed bowel movements.

When constipation in infancy is due to casein curds it is readily overcome by employing some means of preventing the firm coagulation of the casein.

Mellin's Food

acts upon the casein of milk in such a manner that the coagulated casein is presented in a most favorable condition for the action of the digestive fluids; therefore, Mellin's Food is especially indicated in constipation due to faulty protein digestion, and results will at once be apparent if Mellin's Food is used in sufficient amount to thoroughly attenuate the milk casein.

COTTAGE DEPARTMENT

THE LIVERMORE SANITARIUM

HYDROPATHIC DEPARTMENT

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the U. S.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) $45.00 per week and upward.

ANNOUNCES

THAT ITS X-RAY DEPARTMENT IS NOW EQUIPPED

WITH A

MODERN DEEP THERAPY X-RAY APPARATUS

FOR THE

PRE- AND POST-OPERATIVE RADIATION OF DEEP MALIGNANCY

AND THE

TREATMENT OF INOPERABLE MALIGNANT CONDITIONS

This type of apparatus with its ability to produce a voltage of 280,000 volts (about twice the voltage capacity of X-ray machines hitherto available) gives an X-ray beam of enormously magnified penetrating power as compared to those previously in use.

Heavy filtration is used as an added factor in increasing the ratio of the depth to the skin dose, thus markedly decreasing the liability of injurious skin effects while as markedly increasing the effect on the deep tissues.

Insert shows X-Ray Laboratory, Victor Equipped

WHAT X-RAY OUTFIT SHALL BE INSTALLED?

IN THE last twenty years X-Rays have found an ever-widening application in the practice of medicine. X-Rays are now applied in ways undreamed of ten years ago. The result has been that machines of different types have been developed for different diagnostic and therapeutic purposes.

The most important developments in recent years have been the result of the work done in the Research Laboratories at Schenectady, N. Y., which stand behind the Victor X-Ray Corporation and which conduct never-ending investigations to the end that Victor apparatus will always evolve from something that is the best of its time to something still better.

The ranges of service of X-Ray machines that have been developed to meet the needs of physicians and surgeons are so varied that the practitioner is often at a loss to know what particular machine it would be advisable to install. To assist him, the Victor X-Ray Corporation maintains Branch Sales and Service Stations in the principal cities. Any physician or surgeon may call upon these Stations for advice and guidance. A technically informed representative will be sent on request—a representative who studies the practitioner's needs and then recommends the type of machine that will meet them best.

It is the duty of Victor Service Stations, when called upon, to give technical advice to users of Victor machines, so that the desired results are obtained. They also keep the apparatus in good order.

NOTICE—The Executor of the last will of the late Dr. W. S. Hickman (Dr. Hickman in his lifetime was engaged in the general practice of medicine at the village of Georgetown in the County of El Dorado, California, since about 1886 until about some six months ago) wishes to dispose of to some physician and surgeon the library (a small one), surgical instruments and other office and practitioner supplies, and wishes likewise to dispose of the house and lot formerly used as a residence and office. Since Dr. Hickman's death there has been no resident physician there and the nearest practicing physicians are at Placerville, Auburn and Folsom. For further particulars address George H. Thompson, Executor, etc., Placerville, El Dorado County, Calif.

IODALBIN

a protein-iodine compound for internal administration

THE therapeutic effects for which you prescribe iodides are produced most readily by those iodine compounds that are easily split up in the body. It is the available iodine that does the work.

In the case of Iodalbin, contact with the intestinal juice severs the loose bonds that unite the iodine with the protein base.

That's what makes Iodalbin rapidly effective.

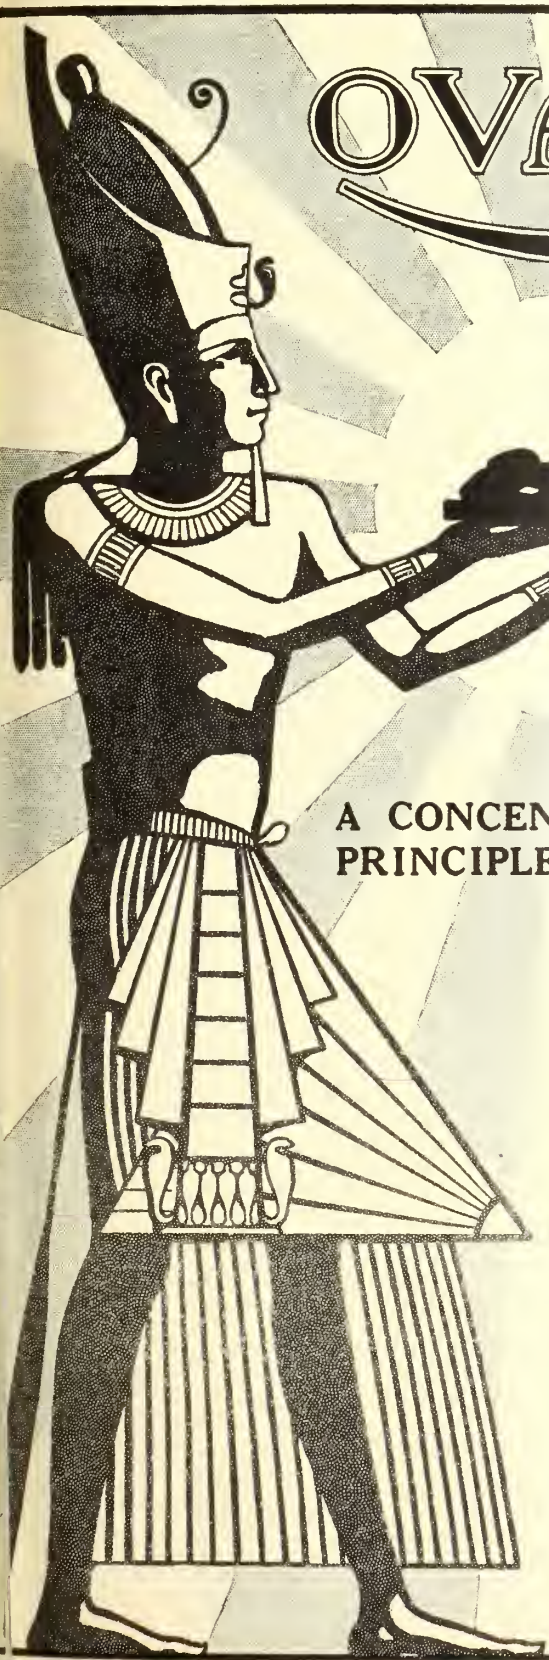
And besides being effective, its blandness makes it acceptable to sensitive patients. It is especially gratifying to those who object to the taste and nauseating effect of sodium or potassium iodide.

A fair average dose for such cases as pleuritic effusion, dry bronchitis, lead poisoning, chronic rheumatic arthritis and the minor degrees of hypothyroidism, is 5 grains, repeated three or four times a day. Even in certain other diseases—cases requiring much larger doses, such as tertiary syphilis and myxedema—Iodalbin can be given with a minimum of discomfort to the patient.

Parke, Davis & Company

Supplied as a powder in ounce vials and in 5-grain capsules.

OVALTINE



A CONCENTRATION OF THE NUTRITIVE PRINCIPLES OF WINTER MALTED BARLEY, EGGS AND MILK.

Presented in the form of golden brown granules, easily soluble, forming a deliciously flavored beverage which appeals to the most fastidious appetite.

A building and restorative nutrient when alimentary function is impaired, as in Convalescence, Phthisis and other wasting diseases, Malnutrition, Fevers, in the Dyscrasias of Pregnancy, and Agalactia.

SOLD BY DRUGGISTS AT 50c, 80c, $1.50 & $5.00.

Samples and Literature Mailed to Physicians Upon Signed Request.

New factory of Reid Bros., Inc., nearing completion at Irvington, California, on San Francisco Bay

Progress must surge ever forward to be called progress.

A LITTLE less than fourteen years ago, two brothers launched a business which has proven to be one of the surprises of modern industry. The story of its rise makes alluring reading. Starting in unpretentious quarters in the city of Seattle, with less than a score of customers, these two men have developed a world-wide business which today numbers among its customers the greatest governments and the greatest hospitals in the world.

The business was started with the sound foundation principal of building good will by building good value. The structure was welded together in the furnace of a white-hot purpose, to not merely sell more

All members of the Medical Profession, Nurses, Hospital Superintendents and Executives and all others interested, are cordially invited to visit our Factories or branches at any time. They will be courteously welcomed and shown an extremely interesting line.

REID

91-99

San Francisco,

supplies, but to sell supplies so honest in quality, equipment so standardized, and service so genuine but that the sum total of their contribution to the cause of human betterment would be really great.

It is good to be able to say to you that Reid Bros.' purpose has not failed, and that their faith in this purpose is being vindicated by everything that is going on in their plants today.

As we write, Reid Bros.' salesmen are traveling the four corners of the globe, postmen are carrying their weekly merchandise message to thirty thousand names, their factory and branches are working night and day under a flood of orders, and workmen are completing a new factory for them at Irvington, Alameda County, California. This addition to their immense works will be the largest and most modernly equipped factory of its kind in America. All is well with Reid Bros., Inc., today, and will continue to be so. Its markets will grow and production increase to meet those markets. Merit will continue to be the determining factor in hospital supplies.

M. L. and R. E. Reid builded well in the beginning and will continue to build well in the future.

Years ago

malpractice insurance was considered an aid if the Doctor happened to have it. If not, he quit practice or moved to another location.

Today

Professional protection is considered a necessity; the Doctor may own property in his own name and practice successfully without worry or loss.

The performance of Specialized Service in Professional Protection exclusively, during these years, is largely responsible for this recognition.

It is interesting to observe that the personnel who guided Medical Protective Service to moral integrity and financial power, continue to labor unceasingly that the Company shall maintain its reputation in fuller measure.

THYROXIN

Prepared only by E. R. SQUIBB & SONS

Under License of the

University of Minnesota

PURE, crystalline Thyroxin is the physiologically active constituent of the thyroid gland; a compound of definite and known chemical composition containing 65 per cent. of iodine, organically combined, as an integral part of the molecule.

Fifteen grains of desiccated thyroid prepared under favorable conditions contains approximately 1/64 grain of Thyroxin. This ratio may be used in determining the initial dose of Thyroxin.

The physiological action of Thyroxin bears a quantitative relation to the production of body energy, and a system that is lacking in such energy may be brought up to normal production by its administration.

Thyroxin is marketed in two forms—Tablets containing the partially purified sodium salt of Thyroxin for oral administration; and the Pure Crystalline Thyroxin for intravenous injection in those cases in which the Thyroxin is not absorbed quantitatively when given by mouth.

Complete Information on Request.

E·R·SQUIBB & SONS, NEW YORK

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

Colfax School for the Tuberculous

Experience has shown that Sanatorium treatment is the most efficient and most approved method of treating the tuberculous. Those patients who are able to take advantage of the superior facilities offered by sanatorium treatment should not be denied the opportunity of receiving these benefits.

The cottage colony of the Colfax School for the Tuberculous provides accommodations for patients who have not only all the advantages of the sanatorium regime and supervision but at the same time have the benefit of home cooking and surroundings. While the patient improves the other members of the family daily receive instructions relative to those things everyone should know regarding tuberculosis.

Information regarding the methods of treatment and other details of interest to the physician and his patient are given in a booklet which will be sent on request.

The Endocrines, Digestive Ferments, Catgut Ligatures, etc.

THE ARMOUR LABORATORY is maintained for the purpose of handling the glands, membranes and other raw materials supplied by our abattoirs in immense quantities, from which important therapeutic agents are extracted and fabricated.

Among the products that the physicians and surgeons use daily are:

Corpus Luteum; Suprarenals, U.S.P.; Parathyroids; Pituitary, Whole Gland; Pituitary, Anterior; Pituitary, Posterior and other glandular substances in po. and tabs. Pituitary Liquid in 1 c. c. and 1-2 c. c. ampoules.

Armour's LABORATORY PRODUCTS

Suprarenalin Solution 1:1000; Suprarenalin Ointment 1:1000; Pepsin, U. S. P.; Pancreatin, U. S. P.; and other preparations of the Digestive Ferments that are used in stomachic and intestinal disorders and as vehicles for nauseating drugs.

We also make Sterile Surgical Catgut Ligatures, plain and chromic, boilable; and Iodized Ligatures, non-boilable. ¶ The Armour ligatures are made from Lamb's gut, selected especially for surgical purposes and sterilized at opportune stages in such manner as to preclude the possibility of contamination in the finished strings.

We are headquarters for the Organotherapeutic Agents and are always glad to co-operate with the medical profession

BALTIMORE—MARYLAND

THE SEXUAL LIFE OF OUR TIME

By IWAN BLOCH, M.D.

PHYSICIAN FOR DISEASES OF THE SKIN, AND FOR DISEASES OF THE SEXUAL SYSTEM, IN CHARLOTTENBURG, BERLIN

AUTHOR OF "THE ORIGIN OF SYPHILIS," ETC.

TRANSLATED BY M. EDEN PAUL, M.D

"A veritable encyclopaedia of the sexual sciences."

"The best book on sexology ever published in any language in the world."—Wm. J Robinson, M.D.

A LITERARY AS WELL AS SCIENTIFIC ACHIEVEMENT

Dr Bloch is a master of style. His book is so well written, so colorful, so vitally absorbing, yet withal so simply told that it would be of immense profit to the layman—BUT FOR ETHICAL REASONS IT IS RESTRICTED TO THE MEDICAL AND LEGAL PROFESSIONS.

The price of the book is $7.00. However, we are allowing physicians 10% discount, making the price $6.30. WE ARE THE SOLE DISTRIBUTORS OF THIS BOOK AT THIS DISCOUNT. Remittance by check, money order, cash or stamps; or sent C. O. D. if desired.

5 DAYS' TRIAL

If not satisfied, return book within 5 days and money will be refunded.

It is invaluable to both specialist and general practitioner because, in addition to throwing new light on the well-defined problems of the former, it strips many baffling cases met with in every-day practice of their deceptive characteristics and reveals the hidden roots of sexual disorder or irregularity.

An investigation of sex and sex manifestations, both normal and pathologic, which not only marks a new epoch in the treatment of patients, but which will be regarded as an authority for countless years to come. From its appearance this book has had a remarkable popularity. In Europe during a recent nine months' period, the sales necessitated six reprintings.

33 Chapters — Only Part of Contents — 800 Pages

I. The Elementary Phenomena of Human Love 7
II The Secondary Phenomena of Human Love (Brain and Senses) 19
III. The Secondary Phenomena of Human Love (Reproductive Organs, Sexual Impulse, Sexual Act) 37
XIX. The Riddle of Homosexuality—Appendix: Theory of Homosexuality. 487
XX. Pseudo-Homosexuality (Greek and Oriental Paederasty, Hermaphroditism, Bisexual Varieties) 537

Subscription prices, including postage, per annum in advance: Domestic, $4.00; Canadian, $5.00.

Domestic rates include United States, Cuba, Mexico, Hawaii, Guam, Porto Rico, Canal Zone and Philippine Islands.

Acceptance for mailing at special rate of postage provided for in Section 1103, Act of October 3, 1917, authorized August 10, 1918.

SINGLE COPIES of this calendar year, 50 cents.

REMITTANCES should be made by check, draft, registered letter, money or express order. Currency should not be sent, unless the letter is registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Medical Society, State of California."

VOLUMES begin with the first of January. Subscriptions may commence at any time.

CHANGE OF ADDRESS notice should give both the old and the new address, and state whether the change is permanent or temporary. The change notice must reach us ten days in advance of the date of the issue which is to be forwarded to the new address.

WARNING: Pay no money to an agent unless he presents a letter showing authority for making collection.

ADVERTISEMENTS.

Advertising forms go to press fifteen days in advance of the date of issue. In sending in copy time must be allowed for setting up advertisements and for sending proofs. No proprietary medicines can be advertised until approved by the Council on Pharmacy and Chemistry. Advertising rates will be sent on request.

CONTRIBUTIONS.

EXCLUSIVE PUBLICATION: Articles are accepted for publication on condition that they are contributed solely to this journal.

CONTRIBUTIONS TYPEWRITTEN: Authors must have their contributions typewritten—double-spaced and with ample margins—before submitting them. The expense is small to the author—the satisfaction is great to the editor and printer. We cannot promise to return unused manuscript, but try to do so in every instance. Manuscript should not be rolled.

ILLUSTRATIONS: Half-tones and zinc etchings, if necessary to elucidate the text, will be furnished by The Journal when satisfactory photographs or drawings are supplied by the author. Each illustration, table, etc., should bear the author's name on the back. Photographs should be clear and distinct; drawings should be made in black ink on white paper. While we cannot guarantee to return used photographs and drawings, we use our best endeavors to do so after the article is published, if the word "return" is written on the back of each.

ANONYMOUS CONTRIBUTIONS, whether for publication, for information, or in the way of criticism, are consigned to the wastebasket unread.

NEWS: Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to physicians. We shall be glad to know the name of the sender in every instance.

Easily adapted to individual infant feeding

in both normal and abnormal conditions

"Horlick's"

The Original Malted Milk

Always clean, safe and reliable. Well balanced, a complete food. Very convenient. Used successfully over one-third of a century.

For the prescribed feeding also of all ages — anaemic, sick and convalescent.

You Can Treat Your Rabies Cases At Home With

RABIES VIRUS, LILLY

Rabies Virus, Lilly, establishes a high degree of immunity. It is harmless; the treatments are free from complications, lessened reactions. The product is uniform. The patient's time and money are economized. Rabies Virus, Lilly, is available for prompt institution of treatment at home by the family physician. Rabies Virus, Lilly, is standardized.

Rabies Virus, Lilly, is supplied in syringe containers, emulsified and ready for instant use. Your druggist can supply the first three doses from the nearest Lilly depot; the remaining eleven doses will be supplied from Indianapolis, one daily, until the complete treatment of fourteen doses has been administered. You can rely on prompt service.

MEAD'S

DIARRHOEA IN INFANTS

SUMMER DIARRHOEA, FERMENTATIVE DIARRHOEA, ETC.

PROTEIN MILK is used in a large number of hospitals and by pediatricians in their private practice to correct diarrhoea in infants. Its value has been fully demonstrated by its use over a period of years. Formerly the preparation of Protein Milk in the home was complicated as well as expensive, which interfered with the doctor's orders being carried out.

MEAD'S CASEC

A new preparation, known as CASEC, has been perfected by MEAD, which makes it possible to do away with the complicated side of preparing Protein Milk. The ease with which Protein Milk can be prepared with Casec has made it practical and widened its use, and now physicians, nurses and mothers may prepare Protein Milk with Casec with the same ease and accuracy as the preparation of any other milk modification in the home.

MEAD'S CASEC is a calcium-caseinate product, prepared from the casein of fresh skimmed milk. Full description, analysis and directions for use will be furnished upon request.

MEAD'S DEXTRI-MALTOSE

for average infant feeding

THE MEAD JOHNSON POLICY

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information regarding their use reaches the mother only by written instructions from her doctor on his private prescription blank. Literature furnished only to physicians.

MEAD'S CASEC

for babies with diarrhoea

Advanced Thought vs. Obsolete Theories

What the MEDICAL INTERPRETER is NOT, is of quite as much concern to the busy practitioner, as what it IS—

The MEDICAL INTERPRETER is NOT a "text book" or cut and dried "set" of text books—

It is NOT an encyclopedia—

It is NOT a set number of books that we offer as a supposed Alpha and Omega of medical research engulfed with the obsoletism of past history; or encumbered with antiquated theories—

NOT any of these—if you please—

The MEDICAL INTERPRETER is a quarterly compilation, profusely illustrated, of the outstanding epochs in European and American medicine and surgery, put in the hands of the busy practitioner while the events and results, recorded in every literal detail, are fresh in the annals of accomplishment; keeping the practitioner in touch with the events of the hour, instead of months and sometimes years thereafter he may finally happen to stumble across the very information of vital importance, recorded in the INTERPRETER while the possibilities of its greatest value might have been enjoyed.

Thus the INTERPRETER is the live chronicler of modern International achievements in medicine and surgery, and given to the fraternity as a quarterly resume of the NEW attitudes and theories, their accomplishments and results.

It will take you but a moment to sign and mail us the attached coupon. Immediately upon receipt we will write you detailed information about the MEDICAL INTERPRETER; or if you request we will mail you the books for free examination and they may be returned at our expense if after ten days you do not believe they will be the valuable acquisition our statements warrant.

City State

Dr. King's Sanatorium

(THE BANNING SANATORIUM)

Banning (Riverside County) California

This well known institution (for the treatment of tuberculosis of the throat and chest) has recently been rebuilt and enlarged. The City of Banning (suffering from phthisiophobia) passed a "zoning" ordinance that forced abandonment of the former site of this sanatorium. A new site was purchased. An injunction was sought to prevent the use of the new site for sanatorium purposes. A temporary injunction was granted but, at the final hearing, this injunction was dissolved and the right to build and maintain the sanatorium was established. Many of the most prominent physicians in the state contributed testimony that enabled us to win the suit. During the progress of these suits the institution found it difficult to provide for patients demanding admission. Now, however, in its new quarters, it is prepared to accept all who apply. To physicians who are unfamiliar with our work we will gladly furnish references to other physicians (in almost every town in California) who have had patients or relatives in this institution. A circular describing conditions and containing rates will be mailed upon request. Address

DRS. KING and BRAMKAMP. BANNING, CALIFORNIA.

HAY FEVER MEMORANDA

LATE SPRING TYPE. Patients whose hay fever develops in the latter part of May, during June or early July, should be tested with the pollens of sweet vernal grass, June grass, orchard grass, timothy and red top. The one giving the major reaction should be selected for treatment to the group. The unrelated rose pollinates simultaneously and is the primary for secondary cause in an occasional case—hence, should be included in tests especially where direct exposure exists. The same is true of dandelion, daisy and in some sections, alfalfa.

LATE SUMMER TYPE. Patients whose hay fever develops in mid-August and continues until frost should be tested with pollens of local importance—primacy being given to the long distance wind pollinated plants, e. g. ragweed. However, where contact is unavoidable, as on a farm, the short distance wind pollinated plants, e. g. corn—and the insect pollinated plants, e. g. sunflower, which are also atmospheric—cannot safely be ignored.

ARLCO—POLLEN EXTRACTS

For **Cutaneous Tests** and **Treatment** cover early and late spring, also summer and autumn.

THE BABY CLARKE is appropriately named. It is a portable gas outfit which the physician can very well take with him as part of his obstetrical equipment. There is constant and legitimate call from women patients that some of the terrors of obstetrical pain be relieved. It is the common practice now in hospitals to use gas for this purpose. THE BABY CLARKE will render the same service to the obstetrician and may be carried to the patient's home and used there or anywhere else.

The portable apparatus is automatic, and requires no attention in analgesia, also used in minor operations. Most progressive men are using Nitrous Oxid-Oxygen in their Obstetrics.

For those patients demanding the use of Radium and X-Ray we are in a position to offer to the medical profession the full and unqualified services of our laboratory. This laboratory is equipped with both Radium element and a complete Emanation plant which enables us to construct any application we may desire to fit the given case. To those physicians wishing to make their own application we are prepared to serve with Radium emanation as they may direct.

Address Dr. D. H. Trowbridge,
Secretary Burnett Sanitarium Co.

CALCREOSE

"CREOSOTE and * * * * are used internally as intestinal and urinary antiseptics, as stimulant expectorants and in the treatment of tuberculosis. Their local irritant actions often interfere with their internal administration." (New and Non-official Remedies, 1921, p. 89.)

CALCREOSE is a mixture containing in loose chemical combination approximately equal weights of creosote and lime (calcium creosotate.)

CALCREOSE administered internally has the same actions and uses as creosote, but does not readily produce gastric distress, nausea and vomiting even when large quantities are taken for comparatively long periods of time.

CALCREOSE may be given in the form of solution or tablets.

ALKALINE THERAPY

CALSO WATER

A sparkling, palatable drinking water rich in ALKALI, and a positive aid to your therapy.

CALSO WATER is made of distilled water and the salts normally present in the human body. It is rich in Calcium and Magnesium, and its use is indicated in all cases of body tissue acidocis. Its merit has been endorsed by many physicians, as it furnishes BASES and SALTS to combine with the acid products of tissue metabolism, thus decreasing their effect on the body and favoring their elimination.

Samples to physicians upon written request

THE KROMAYER LAMP

Consider—

that the Kromayer lamp enjoys the distinction for highest intensity of Ultra-Violet radiation and the most practical means for administering treatment of many conditions.

The effective results obtained with its use over a period of ten years has been the stimulant for our scientific research work that has resulted in bringing the lamp to its present high state of efficiency.

It is chosen as the most desirable method of applying actinic rays to Lupus, Naevus, Acne, Psoriasis, Eczema, Ulcers and Wounds; to specific or non-specific orificial inflammatory conditions such as Tubercular Laryngitis, Rectal Fistulae, Otitis Media, Frontal Sinus Infections, Ozena and a number of gynecological conditions.

San Francisco, Cal.

THE MORTON HOSPITAL announces that they have purchased the former McNUTT or FAIRMONT HOSPITAL, 1055 Pine Street, San Francisco, and it is now open to the Medical Profession under the co-operative plan, and will be known as the SANTA FE HOSPITAL. The hospital has been thoroughly modernized and equipped with four Operating Rooms, Hydro-therapy, Electro-therapy, Thermo-penetration, Helio-therapy, X-ray, Pathological and Clinical Laboratories.

Every physician will have equal privileges in the hospital

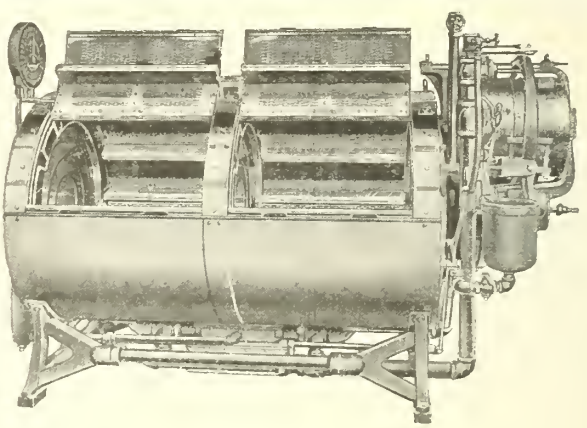
—"the most efficient and economical ever built"

In these words the physician-in-chief of a prominent hospital sums up his opinion of the Henrici Bronze Washer, which has been in operation in that institution's laundry for the past six years.



A large amount of this laundry work is from infectious disease, which is disinfected by boiling in the Henrici for thirty minutes. The Henrici has effected a material saving of water, soap, blueing and all other material.

Send for special circular

MADE IN THE GOOD OLD U. S. A.

A Thoroughly Soft, Pliable, Transparent

DRESSING MATERIAL

Cellosilk is a product developed by American Science to meet the long felt need of the medical profession for a suitable dressing of this kind. It is prepared from Cotton, Gums, and carefully blended, is suitable for all dressing purposes.

PERFORATED AND IMPERVIOUS FORMS

Impervious Cellosilk is used as a protective covering over all wet and moist dressings, as a direct Impervious dressing where such is indicated, and for drains.

Perforated Cellosilk is used as a direct, non-adherent dressing for all granulating wounds; burns, skin grafts, ulcers, mastoid operations, etc.

Secure Cellosilk from your regular supply house. Both Perforated and Impervious forms should be on hand at all times for use as needed.

Marshalltown Laboratories, Inc. **Marshalltown, Iowa.**

"DIRECT BY MAIL ADVERTISING"

PHYSICIANS everywhere are complaining of the annoyance of the enormous amount of advertising literature that is coming to them directly by mail. It is believed that members of our society would best conserve their time and energies by throwing every bit of this character of mail into the waste basket without bothering to open it. From the recent extensive trip of the editor through the southern part of the State, when more than 1000 physicians were interviewed, it is believed that most physicians already discard this great volume of advertising matter without ever taking the trouble to open it.

The advertising columns of creditable medical journals (including your own State Journal and Better Health in California) are open to the advertisers of any ethical product. The advertisements are arranged so as to be readily accessible, and persons with ethical articles for sale ought to be glad of this easy method of approach to members of the profession.

We know there are a number of ethical firms that seem to prefer to sell directly to our membership and who hesitate to pay for space in our official Journal. There are a larger number of unethical firms, offering questionable products, that the Publicity Bureau, which controls the advertising policies of the California State Journal, has occasion to refuse space in our columns.

The Publicity Bureau suggests in the interests of better medicine that, when our members are approached by postal card or other one-cent postage propaganda issued by firms whose names do not appear in the Journal, inquiry should be made as to their standing and reliability. The office of the Journal is continually gathering information on this and other subjects that is available for our members.

Beautify Your Offices

A DOCTOR'S OFFICE equipped with beautiful white, washable steel furniture radiates sanitation, order and technical efficiency. Such surroundings place the Doctor in good working humor and improves his technique. But, most important of all, is the pleasing mental attitude white, steel equipment produces in the patient's mind.

The seven-piece office furniture set shown above has been designed, constructed and priced to enable the profession to discard their obsolete equipment and install modern furniture. Only the finest of materials and workmanship enter into its construction. Silver furniture steel is used—all metal trimmings are heavily plated with non-rustable nickel—the white enamel is put on in six or more coats, oven baked, and all surfaces can be scoured like a dish. This set will give constant year-in-year-out service and—

It Costs Only $154.75

We send the set on 15 days' free inspection. If it is not what we claim, we take it back, pay the freight charges both ways, and the transaction will not cost you a penny. Don't overlook this opportunity to modernize your offices at this low cost. Fill in and mail the coupon below and we will send you an illustrated booklet giving description and measurements of each piece and telling more about the terms.

HAY-FEVER

CAN BE ALLEVIATED AND IN MANY CASES PREVENTED BY EARLY TREATMENT WITH AN EFFICIENT PROPHYLACTIC. THE TREATMENT SHOULD BE STARTED SIX WEEKS IN ADVANCE OF THE ANTICIPATED ATTACK

POLLEN ANTIGENS - *Lederle*

Are prepared by extracting the dried pollen in 66 2/3 per cent glycerol and 33 1/3 per cent saturated sodium chloride solution. *This ensures their uniform stability.*

They are standardized against antipollen serum by the complement fixation method which accurately determines the amount of antigenically active pollen protein. *This ensures their antigenic activity and provides for accurate dosage.*

Pollen Antigens-Lederle are supplied to the physician in accurately measured doses, properly preserved, each dose accompanied by a vial of sterile diluent. The antigen and diluent are not mixed until just before injection, thus guarding against the loss of specific antigenic properties.

The Early Diagnosis of Typhoid Fever

While the clinical value of the agglutination test of Widal remains the same as it ever was, and it is undoubtedly a useful diagnostic procedure in the demonstration of the presence of a typhoid infection, it is now quite outclassed by a more dependable diagnostic procedure. **The blood culture is the best means of detecting typhoid fever—EARLY.**

Cultures of the blood from a suspected typhoid patient give us definite information as to whether a given individual is suffering with an infection with the Eberth bacillus. This quite overshadows the Widal test in importance because it gives us the same information a number of days earlier—and the element of time is quite the most important in initiating an effective course of treatment. This all-important time element has about eliminated the Widal test save only in exceptional cases.

The Blood Culture offers more definite information and permits an early diagnosis; 90 per cent of cases will give a positive blood culture during the first week.

The Widal reaction appears so late that it is never much more than confirmatory. Also, on account of the wide application of prophylactic typhoid vaccination among the general population, the value of the Widal test is limited. People who have received prophylactic treatment give a positive Widal for some time.

The Leukocyte Count is also of diagnostic value in suspected typhoid cases, for a leukopenia is usually found in typhoid.

We will be glad to furnish containers for the collection of specimens for any of the above tests.

Blood Culture for Typhoid	$5.00
White and Diff. Leukocyte Count	2.50
Widal Reaction	2.00

The Management of an Infant's Diet

Diarrhea

The importance of nourishment in intestinal disturbances that are so common during the warm weather is now recognized by physicians, and it is also appreciated that the nutrition furnished must be somewhat different than the milk modification usually supplied to the normal infant.

Food elements that seem to be particularly well adapted, mixtures that are suitable to meet the usual conditions, and the general management of the diet, are described in our pamphlet—"The Feeding of Infants in Diarrhea"—a copy of which will be sent to any physician who desires to become familiar with a rational procedure in summer diarrhea.

COTTAGE DEPARTMENT

THE LIVERMORE SANITARIUM

HYDROPATHIC DEPARTMENT

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the U. S.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) $45.00 per week and upward.

ANNOUNCES

THAT ITS X-RAY DEPARTMENT IS NOW EQUIPPED

WITH A

MODERN DEEP THERAPY X-RAY APPARATUS

FOR THE

PRE- AND POST-OPERATIVE RADIATION OF DEEP MALIGNANCY

AND THE

TREATMENT OF INOPERABLE MALIGNANT CONDITIONS

This type of apparatus with its ability to produce a voltage of 280,000 volts (about twice the voltage capacity of X-ray machines hitherto available) gives an X-ray beam of enormously magnified penetrating power as compared to those previously in use.

Heavy filtration is used as an added factor in increasing the ratio of the depth to the skin dose, thus markedly decreasing the liability of injurious skin effects while as markedly increasing the effect on the deep tissues.

CORRESPONDENCE AND INSPECTION BY THE PROFESSION IS INVITED

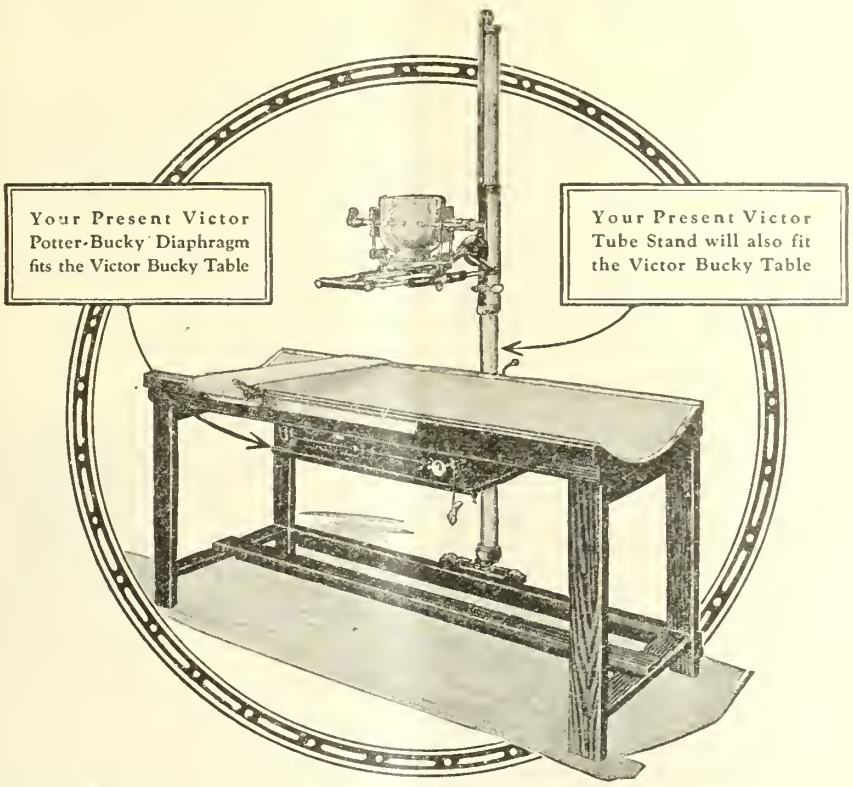
W. H. HILL, M. D., Resident Physician



Victor Improvements Will Fit Your Present Victor Apparatus

THE research systematically conducted by the Victor X-Ray Corporation results in the development of many improvements. No physician wishes the science of Roentgenology, so dependent on apparatus, to stand still.

But what of the physician who has bought a complete Victor equipment, only to find, a few months later, that improvements have been made? Must he install an entirely new equipment in order to keep abreast of the times?

It has been the policy of the Victor X-Ray Corporation, wherever possible, to design apparatus and their accessories so that *improvements may be adapted to existing apparatus* without the necessity of discarding an entire equipment. In a word, Victor apparatus is standardized.

Take the Victor Bucky Table, for example. This table will readily accommodate the Victor Model Potter-Bucky Diaphragm; any Victor tube stand can also be attached in a few minutes. Thus, in instances where the X-Ray Laboratory already has the Victor Diaphragm and Tube Stand, the only expense involved is the table itself.

So, standardization of Victor apparatus makes it possible for the physician to take advantage of the latest developments of research without completely discarding his X-Ray equipment.

VICTOR X-RAY CORPORATION, Jackson Blvd. at Robey St., Chicago

OUR SAN FRANCISCO OFFICE, 254 SUTTER STREET, WILL GLADLY GIVE YOU FULL INFORMATION ON THE VICTOR DEEP THERAPY X-RAY APPARATUS AS USED IN ST. LUKE'S HOSPITAL, SAN FRANCISCO, AS MENTIONED IN THEIR ANNOUNCEMENT ON OPPOSITE PAGE.

Adrenalin

The Emergency Remedy

TWENTY years ago the chemical formula for Adrenalin was worked out by our research chemists. That discovery alone assured the renascence of endocrinology—this time as a serious scientific study.

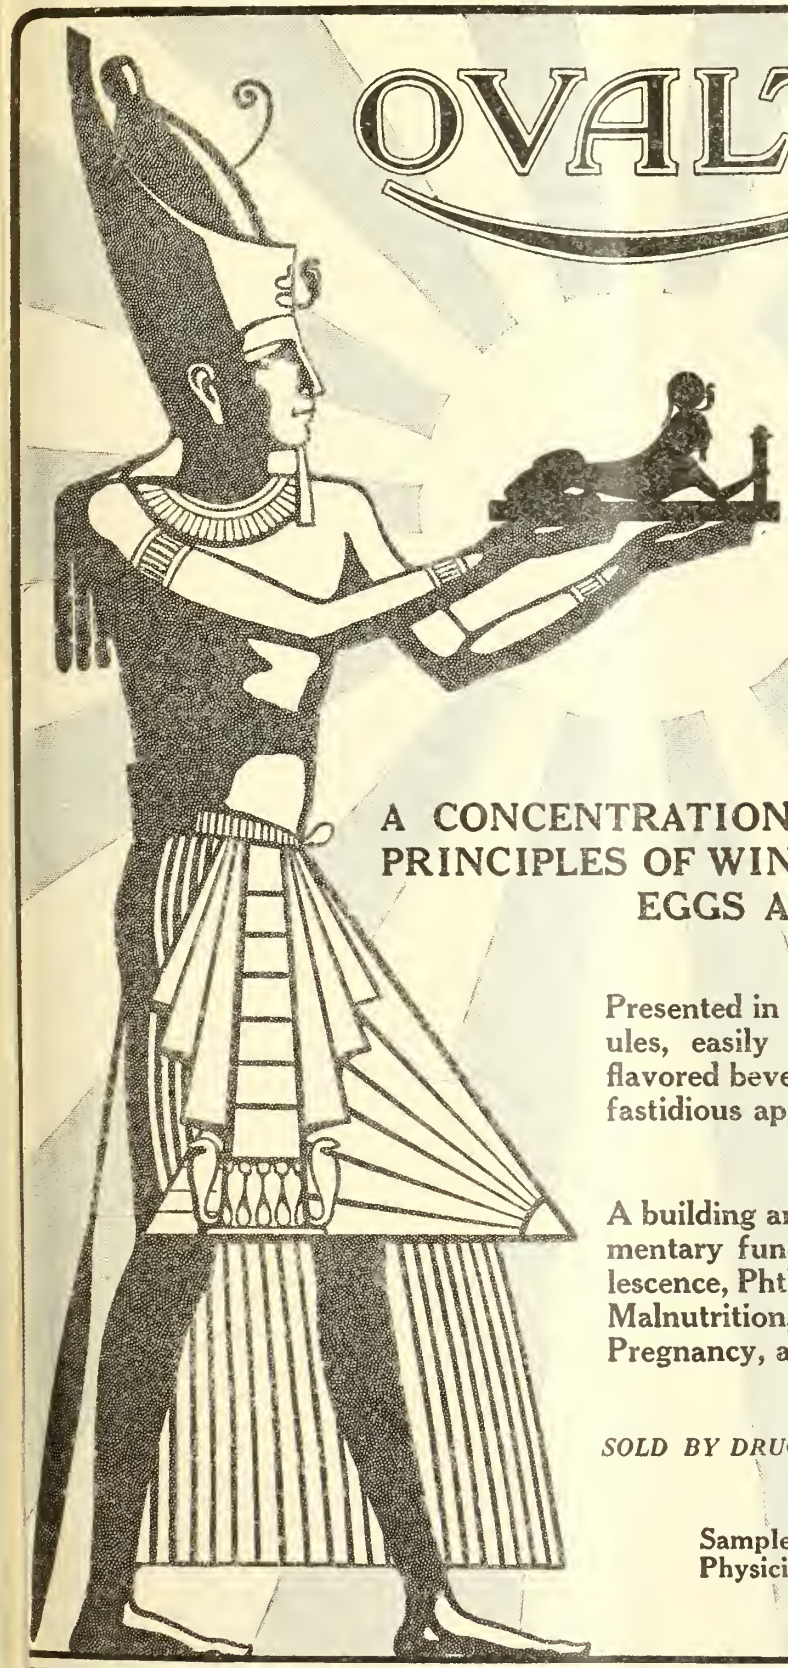
More thought and work and expense have been lavished on determining the exact pharmacology of Adrenalin than on any of the other hormones.

Today Adrenalin is entrenched in the Materia Medica side by side with such indispensable remedies as digitalis and quinine.

Adrenalin is essentially an emergency drug, and its main indications are in the treatment of shock, hemorrhage, and the paroxysm of asthma. It is used advantageously in connection with local anesthetics. Its unfailing action forms the basis for certain diagnostic procedures, such as the Goetsch test and the test for adrenal hypersensitiveness.

Parke, Davis & Company

OVALTINE



A CONCENTRATION OF THE NUTRITIVE PRINCIPLES OF WINTER MALTED BARLEY, EGGS AND MILK.

Presented in the form of golden brown granules, easily soluble, forming a deliciously flavored beverage which appeals to the most fastidious appetite.

A building and restorative nutrient when alimentary function is impaired, as in Convalescence, Phthisis and other wasting diseases, Malnutrition, Fevers, in the Dyscrasias of Pregnancy, and Agalactia.

SOLD BY DRUGGISTS AT 50c, 80c, $1.50 & $5.00.

Samples and Literature Mailed to Physicians Upon Signed Request.

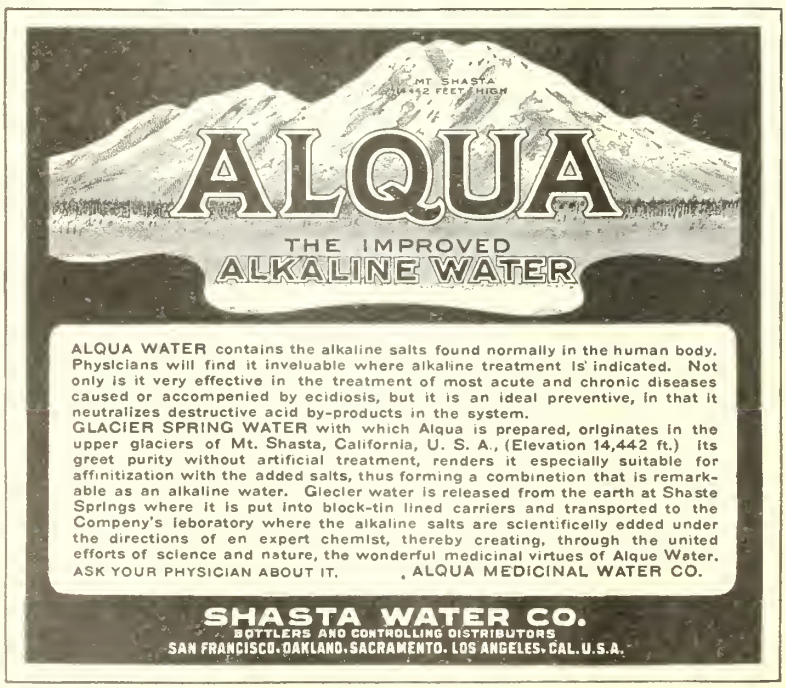
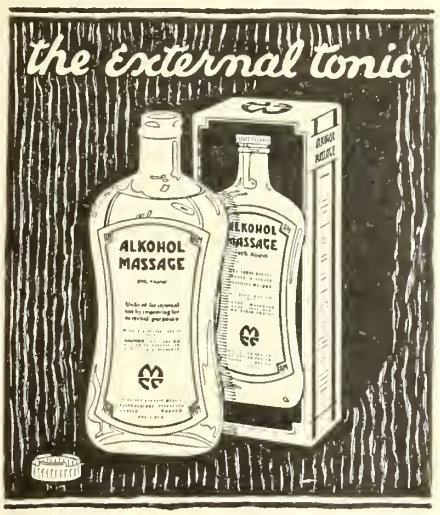
Large clinical experience conducted by clinicians of note has established the superior efficiency of ALQUA in overcoming the disagreeable and dangerous symptoms of Acidosis in—



- pre- and post-operative conditions
- pre- and post-partum conditions
- infectious diseases
- hyperacid stomach conditions
- headache, due to high acidity
- headache, due to brain oedema
- skin conditions
- genito-urinary infection
- edema—local or general nephritis
- diabetes
- asthma and hay-fever
- arterio-sclerosis
- clyclic vomiting
- alcoholism
- typhoid bacilli
- children and in infantile diarrhoea.

At All Druggists

95% Ethyl Alcohol



An Important Development

In the Medication of Alcohol

After lengthy research, the Mifflin Chemists have evolved a private formula which removes every drawback from the prescription of medicated alcohol.

Soothing and Odorless

Alkohol Massage, the result of the new formula, is really better than the old alcohol for external purposes. No wood alcohol, acetone, or other poisonous ingredients. Pleasant odor. Soothing, not injurious to the skin.

ALKOHOL MASSAGE

Physicians' samples gladly sent on request will show how satisfactory it is.

THYROXIN

Prepared only by E. R. SQUIBB & SONS

Under License of the

University of Minnesota

PURE, crystalline Thyroxin is the physiologically active constituent of the thyroid gland; a compound of definite and known chemical composition containing 65 per cent. of iodine, organically combined, as an integral part of the molecule.

Fifteen grains of desiccated thyroid prepared under favorable conditions contains approximately 1/64 grain of Thyroxin. This ratio may be used in determining the initial dose of Thyroxin.

The physiological action of Thyroxin bears a quantitative relation to the production of body energy, and a system that is lacking in such energy may be brought up to normal production by its administration.

Thyroxin is marketed in two forms—Tablets containing the partially purified sodium salt of Thyroxin for oral administration; and the Pure Crystalline Thyroxin for intravenous injection in those cases in which the Thyroxin is not absorbed quantitatively when given by mouth.

Complete Information on Request.

Colfax School for the Tuberculous

Experience has shown that Sanatorium treatment is the most efficient and most approved method of treating the tuberculous. Those patients who are able to take advantage of the superior facilities offered by sanatorium treatment should not be denied the opportunity of receiving these benefits.

The cottage colony of the Colfax School for the Tuberculous provides accommodations for patients who have not only all the advantages of the sanatorium regime and supervision but at the same time have the benefit of home cooking and surroundings. While the patient improves the other members of the family daily receive instructions relative to those things everyone should know regarding tuberculosis.

Information regarding the methods of treatment and other details of interest to the physician and his patient are given in a booklet which will be sent on request.

Subscription prices, including postage, per annum in advance: Domestic, $4.00; Canadian, $5.00.

Domestic rates include United States, Cuba, Mexico, Hawaii, Guam, Porto Rico, Canal Zone and Philippine Islands.

Acceptance for mailing at special rate of postage provided for in Section 1103, Act of October 3, 1917, authorized August 10, 1918.

SINGLE COPIES of this calendar year, 50 cents.

REMITTANCES should be made by check, draft, registered letter, money or express order. **Currency should not be sent unless the letter is registered.** Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Medical Society, State of California."

VOLUMES begin with the first of January. Subscriptions may commence at any time.

CHANGE OF ADDRESS notice should give both the old and the new address, and state whether the change is permanent or temporary. The change notice must reach us ten days in advance of the date of the issue which is to be forwarded to the new address.

WARNING: Pay no money to an agent unless he presents a letter showing authority for making collection.

ADVERTISEMENTS.

Advertising forms go to press fifteen days in advance of the date of issue. In sending in copy time must be allowed for setting up advertisements and for sending proofs. No proprietary medicines can be advertised until approved by the Council on Pharmacy and Chemistry. Advertising rates will be sent on request.

CONTRIBUTIONS.

EXCLUSIVE PUBLICATION: Articles are accepted for publication on condition that they are contributed solely to this journal.

CONTRIBUTIONS TYPEWRITTEN: Authors must have their contributions typewritten—double-spaced and with ample margins—before submitting them. The expense is small to the author—the satisfaction is great to the editor and printer. We cannot promise to return unused manuscript, but try to do so in every instance. **Manuscript should not be rolled.**

ILLUSTRATIONS: Half-tones and zinc etchings, if necessary to elucidate the text, will be furnished by The Journal when satisfactory photographs or drawings are supplied by the author. Each illustration, table, etc., should bear the author's name on the back. Photographs should be clear and distinct; drawings should be made in black ink on white paper. While we cannot guarantee to return used photographs and drawings, we use our best endeavors to do so after the article is published, if the word "return" is written on the back of each.

ANONYMOUS CONTRIBUTIONS, whether for publication, for information, or in the way of criticism, are consigned to the wastebasket unread.

NEWS: Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to physicians. We shall be glad to know the name of the sender in every instance.

MEAD'S

DIARRHOEA IN INFANTS

SUMMER DIARRHOEA, FERMENTATIVE DIARRHOEA, ETC.

PROTEIN MILK is used in a large number of hospitals and by pediatricians in their private practice to correct diarrhoea in infants. Its value has been fully demonstrated by its use over a period of years. Formerly the preparation of Protein Milk in the home was complicated as well as expensive, which interfered with the doctor's orders being carried out.

MEAD'S CASEC

A new preparation, known as CASEC, has been perfected by MEAD, which makes it possible to do away with the complicated side of preparing Protein Milk. The ease with which Protein Milk can be prepared with Casec has made it practical and widened its use, and now physicians, nurses and mothers may prepare Protein Milk with Casec with the same ease and accuracy as the preparation of any other milk modification in the home.

MEAD'S CASEC is a calcium-caseinate product, prepared from the casein of fresh skimmed milk. Full description, analysis and directions for use will be furnished upon request.

MEAD'S DEXTRI-MALTOSE

for average infant feeding

THE MEAD JOHNSON POLICY

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information regarding their use reaches the mother only by written instructions from her doctor on his private prescription blank. Literature furnished only to physicians.

MEAD'S CASEC

for babies with diarrhoea

Advanced Thought vs. Obsolete Theories

What the MEDICAL INTERPRETER is NOT, is of quite as much concern to the busy practitioner, as what it IS—

The MEDICAL INTERPRETER is NOT a "text book" or cut and dried "set" of text books—

It is NOT an encyclopedia—

It is NOT a set number of books that we offer as a supposed Alpha and Omega of medical research engulfed with the obsoletism of past history; or encumbered with antiquated theories—

NOT any of these—if you please—

The MEDICAL INTERPRETER is a quarterly compilation, profusely illustrated, of the outstanding epochs in European and American medicine and surgery, put in the hands of the busy practitioner while the events and results, recorded in every literal detail, are fresh in the annals of accomplishment; keeping the practitioner in touch with the events of the hour, instead of months and sometimes years thereafter he may finally happen to stumble across the very information of vital importance, recorded in the INTERPRETER while the possibilities of its greatest value might have been enjoyed.

Thus the INTERPRETER is the live chronicler of modern International achievements in medicine and surgery, and given to the fraternity as a quarterly resume of the NEW attitudes and theories, their accomplishments and results.

It will take you but a moment to sign and mail us the attached coupon. Immediately upon receipt we will write you detailed information about the MEDICAL INTERPRETER; or if you request we will mail you the books for free examination and they may be returned at our expense if after ten days you do not believe they will be the valuable acquisition our statements warrant.

Dr. King's Sanatorium

(THE BANNING SANATORIUM)

Banning (Riverside County) California

This well known institution (for the treatment of tuberculosis of the throat and chest) has recently been rebuilt and enlarged. The City of Banning (suffering from phthisiophobia) passed a "zoning" ordinance that forced abandonment of the former site of this sanatorium. A new site was purchased. An injunction was sought to prevent the use of the new site for sanatorium purposes. A temporary injunction was granted but, at the final hearing, this injunction was dissolved and the right to build and maintain the sanatorium was established. Many of the most prominent physicians in the state contributed testimony that enabled us to win the suit. During the progress of these suits the institution found it difficult to provide for patients demanding admission. Now, however, in its new quarters, it is prepared to accept all who apply. To physicians who are unfamiliar with our work we will gladly furnish references to other physicians (in almost every town in California) who have had patients or relatives in this institution. A circular describing conditions and containing rates will be mailed upon request. Address

DRS. KING and BRAMKAMP. BANNING, CALIFORNIA.

HAY FEVER MEMORANDA

Series II

LATE SPRING TYPE. Patients whose hay fever develops in the latter part of May, during June or early July, should be tested with the pollens of sweet vernal grass, June grass, orchard grass, timothy and red top. The one giving the major reaction should be selected for treatment to the group. The unrelated rose pollinates simultaneously and is the primary or secondary cause in an occasional case—hence, should be included in tests especially where direct exposure exists. The same is true of dandelion, daisy and in some sections, alfalfa.

LATE SUMMER TYPE. Patients whose hay fever develops in mid-August and continues until frost should be tested with pollens of local importance—primacy being given to the long distance wind pollinated plants, e. g. ragweed. However, where contact is unavoidable, as on a farm, the short distance wind pollinated plants, e. g. corn—and the insect pollinated plants, e. g. sunflower, which are also atmospheric—cannot safely be ignored.

ARLCO—POLLEN EXTRACTS

For **Cutaneous Tests** and **Treatment** cover early and late spring, also summer and autumn.

RADIUM
AND
ONCOLOGIC INSTITUTE

1151 WEST SIXTH STREET
LOS ANGELES

A THOROUGHLY EQUIPPED INSTITUTION affording unexcelled facilities for the scientific administration of Radium Therapy and the study and treatment of Neoplastic diseases.

THE NEW AND MODERN FIREPROOF BUILDING contains private rooms for bed and ambulatory cases, completely equipped examination and treatment rooms, Roentgen Ray, clinical and research laboratories.

THE RADIUM LABORATORY, in addition to a large and adequate quantity of Radium, is equipped with a Duane emanation apparatus and all necessary appliances, affording the most modern and complete facilities for Radium Therapy.

THIS INSTITUTION, substantially endowed, is in its equipment and capacity equal to any other in this country, and is the largest and most complete in the United States, devoted exclusively to this work.

WE DESIRE TO CONFER and cooperate with the medical profession regarding the use of Radium in appropriate cases.

THE BABY CLARKE is appropriately named. It is a portable gas outfit which the physician can very well take with him as part of his obstetrical equipment. There is constant and legitimate call from women patients that some of the terrors of obstetrical pain be relieved. It is the common practice now in hospitals to use gas for this purpose. THE BABY CLARKE will render the same service to the obstetrician and may be carried to the patient's home and used there or anywhere else.

The portable apparatus is automatic, and requires no attention in analgesia, also used in minor operations. Most progressive men are using Nitrous Oxid-Oxygen in their Obstetrics.

Burnett Sanitarium

Fresno, California

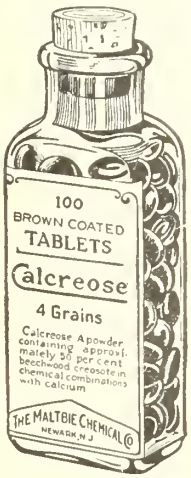
For those patients demanding the use of Radium and X-Ray we are in a position to offer to the medical profession the full and unqualified services of our laboratory. This laboratory is equipped with both Radium element and a complete Emanation plant which enables us to construct any application we may desire to fit the given case. To those physicians wishing to make their own application we are prepared to serve with Radium emanation as they may direct.

Address Dr. D. H. Trowbridge,
Secretary Burnett Sanitarium Co.

CALCREOSE

Calcium in Intestinal Tuberculosis

"The administration of calcium chlorid in tuberculous diarrhea is, we believe, based on empiricism, but of its good effects there are at present many undeniable examples. . . . We have used calcium chlorid in no sense as a curative agent, but merely as a palliative in an attempt to control the distressing symptoms of pain and diarrhea." —**P. H. Ringer** and **C. I. Minor**, Am. Rev. Tuberc., 5:876 (Jan.) 1922.



CALCREOSE (calcium creosotate) is a mixture containing in loose chemical combination approximately equal parts of creosote and lime.

CALCREOSE has the same actions and uses as creosote but is free from its untoward effects on the stomach. Creosote is used as an intestinal antiseptic.

THE ALPINE SUN LAMP

THE Alpine Sun Lamp illustrated above presents the most convenient source of Intense Ultra-Violet Light known at the present time.
Its field of indications covers Tuberculosis in most of its manifestations, superficial skin lesions, nervous diseases, post-operative infections, osteomyelitis, sluggish ulcers, and conditions resulting from faulty metabolism.

Standard

SINCE the advent of the Alpine Sun Lamp over a decade ago the high standard set for it has always been upheld.

Long researches by us and clinical tests made by users, have made this lamp an instrument of physical and mechanical precision, particularly typified by the model shown in the accompanying illustration.

And the consistent good work continues!

The Grande Vista Sanatorium

Announcement of Expansion and Reorganization

THE GRANDE VISTA SANATORIUM is beautifully situated in the foothills above Richmond in a thirty-acre park. The buildings are attractive and the surroundings restful. The sanatorium has been and is being operated successfully as a private sanatorium for nervous patients.

The management announces that a program of expansion is being inaugurated. The accommodations for patients and the variety of patients are being increased.

Physicians are invited to interest themselves in this new program. Physicians who send patients to the sanatorium will continue in charge of the patient under a plan of co-operation of mutual advantage to the patient and the physician.

CALIFORNIA STATE JOURNAL OF MEDICINE

RESOLUTION ON "STATE MEDICINE"

"THE AMERICAN MEDICAL ASSOCIATION hereby declares its opposition to all forms of 'state medicine,' because of the ultimate harm that would come thereby to the public weal through such form of medical practice.

" 'State medicine' is hereby defined for the purpose of this resolution to be any form of medical treatment, provided, conducted, controlled or subsidized by the federal or any state government, or municipality, excepting such service as is provided by the Army, Navy, or Public Health Service, and that which is necessary for the control of communicable diseases, the treatment of mental disease, the treatment of the indigent sick, and such other services as may be approved by and administered under the direction of or by a local county medical society, and are not disapproved by the state medical society of which it is a component part." (*Abstract from Minutes of the Seventy-third Annual Session of the A. M. A.*)

Beautify Your Offices

A DOCTOR'S OFFICE equipped with beautiful white, washable steel furniture radiates sanitation, order and technical efficiency. Such surroundings place the Doctor in good working humor and improves his technique. But, most important of all, is the pleasing mental attitude white, steel equipment produces in the patient's mind.

The seven-piece office furniture set shown above has been designed, constructed and priced to enable the profession to discard their obsolete equipment and install modern furniture. Only the finest of materials and workmanship enter into its construction. Silver furniture steel is used—all metal trimmings are heavily plated with non-rustable nickel—the white enamel is put on in six or more coats, oven baked, and all surfaces can be scoured like a dish. This set will give constant year-in-year-out service and—

It Costs Only $154.75

We send the set on 15 days' free inspection. If it is not what we claim, we take it back, pay the freight charges both ways, and the transaction will not cost you a penny. Don't overlook this opportunity to modernize your offices at this low cost. Fill in and mail the coupon below and we will send you an illustrated booklet giving description and measurements of each piece and telling more about the terms.

HAY-FEVER

CAN BE ALLEVIATED AND IN MANY CASES PREVENTED BY EARLY TREATMENT WITH AN EFFICIENT PROPHYLACTIC. THE TREATMENT SHOULD BE STARTED SIX WEEKS IN ADVANCE OF THE ANTICIPATED ATTACK

POLLEN ANTIGENS - *Lederle*

Are prepared by extracting the dried pollen in 66 2/3 per cent glycerol and 33 1/3 per cent saturated sodium chloride solution. *This ensures their uniform stability.*

They are standardized against antipollen serum by the complement fixation method which accurately determines the amount of antigenically active pollen protein. *This ensures their antigenic activity and provides for accurate dosage.*

Pollen Antigens-Lederle are supplied to the physician in accurately measured doses, properly preserved, each dose accompanied by a vial of sterile diluent. The antigen and diluent are not mixed until just before injection, thus guarding against the loss of specific antigenic properties.

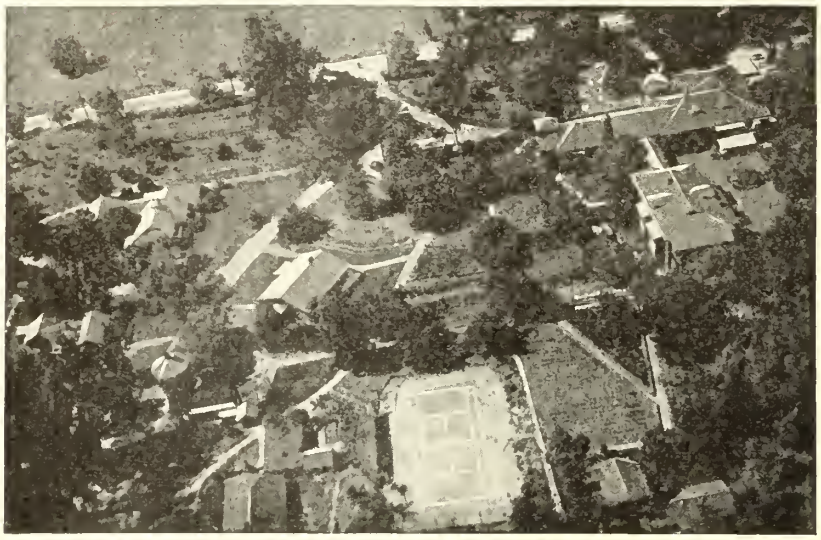
PASADENA, CALIFORNIA



AIRPLANE VIEW OF GROUNDS

A SANITARIUM FOR THE TREATMENT OF ALL FORMS OF NERVOUS DISORDERS AND GENERAL DISEASES

SIXTEEN MILES FROM LOS ANGELES, HEART OF THE ORANGE BELT

MAIN BUILDING

LOCATION—Situated in the foothills of the Sierra Madre Mountains, just outside of the city of Pasadena, is this beautiful sanitarium. It is surrounded by a natural live-oak grove of 20 acres, with lawns and gardens, ideally adapted to rest and enjoyment. Large central building and cottages all modernly equipped. Homelike and comfortable.

Climate Ideal.
Cuisine Excellent.
Outdoor Sports and Recreation.

EQUIPMENT—Special equipment for aiding in a correct diagnosis. The Laboratory, Hydrotherapy and Electricity Departments are important adjuncts to the general Sanitarium treatment. All forms of baths are given, including the famous Nauheim.

Dairy and Poultry Plant.
Rooms With or Without Baths.
Private Bungalows With Sleeping Porches.

CLASS OF PATIENTS — All forms of nervous disorders and general diseases are treated. Special attention is paid to Gastro-Intestinal disorders and Circulatory System. No Tuberculosis, Epilepsy or Insanity received.

BOARD OF DIRECTORS.— Norman Bridge, M. D., H. C. Brainerd, M. D., W. Jarvis Barlow, M. D., F. C. E. Mattison, M. D., Stephen Smith, M. D.

The Management of an Infant's Diet

Diarrhea of Infants

Three recommendations are made—

Stop at once the giving of milk.
Thoroughly clean out the intestinal tract.
Give nourishment composed of food elements capable of being absorbed with minimum digestive effort.

A diet that meets the condition is prepared as follows:

Mellin's Food . . **4 level tablespoonfuls**
Water (boiled, then cooled) . **16 fluidounces**

Feed small amounts at frequent intervals.

It is further suggested:—As soon as the stools lessen in number and improve in character, gradually build up the diet by substituting one ounce of skimmed milk for one ounce of water until the amount of skimmed milk is equal to the quantity of milk usually given for the age of the infant; also that no milk fat be given until the baby has completely recovered.

Mellin's Food Company, Boston, Mass.

HYDROPATHIC DEPARTMENT

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

COTTAGE DEPARTMENT

THE LIVERMORE SANITARIUM

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the U. S.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) $45.00 per week and upward.

ANNOUNCES

THAT ITS X-RAY DEPARTMENT IS NOW EQUIPPED

WITH A

MODERN DEEP THERAPY X-RAY APPARATUS

FOR THE

PRE- AND POST-OPERATIVE RADIATION OF DEEP MALIGNANCY

AND THE

TREATMENT OF INOPERABLE MALIGNANT CONDITIONS

This type of apparatus with its ability to produce a voltage of 280,000 volts (about twice the voltage capacity of X-ray machines hitherto available) gives an X-ray beam of enormously magnified penetrating power as compared to those previously in use.

Heavy filtration is used as an added factor in increasing the ratio of the depth to the skin dose, thus markedly decreasing the liability of injurious skin effects while as markedly increasing the effect on the deep tissues.

Buying Power
of Our Members

There are 3842 members of the Medical Society of the State of California and readers of this Journal, located in every important city and town of this State.

This means 3842 circles of practice, which touch and influence over 1,921,000 people in the homes, industries and institutions throughout the State.

Think of the BUYING POWER of these physicians! If their average expenditure is only $1000, that amounts to $3,842,000 a year. But medical supplies bought on physicians' prescriptions, and goods purchased on their orders or recommendations for Sanitariums, Hospitals, Boards of Health, etc., would fully equal that amount—or a total of $7,500,000.

If members will give preference in all their buying to advertisers in their State Medical Journal, other advertisers will want space, and the publishers can then print a LARGER and BETTER Journal.

If you do not find advertised here the goods you want, please write the Journal. We will secure the information for you.

THE SANITARIUM WITH A PERSONALITY

Address all communications to Medical Director, Ross Sanitarium, Ross, California

CHLORETONE
the *sensible* hypnotic

THE frequency with which you find indications for the exhibition of hypnotics makes it essential that your favorite remedy in this class be broadly serviceable—produce results you can count on, and give rise to a minimum of discomfort.

That's why many of your fellow practitioners have for years relied on Chloretone.

Prescribe Chloretone in doses of 5 to 20 grains—always in capsules, because the crystals are volatile. Prescribe the larger doses in cases of delirium, convulsions, uremia, tetanus, and hydrophobia. The smaller doses are required in cases of insomnia and restlessness, and in the symptomatic treatment of epilepsy. Chloretone is especially efficacious in combating seasickness and gastric irritability.

Parke, Davis & Company

A Booklet on the subject of Pertussis Vaccines.

Gladly sent physicians on request.

Gastric Disorders

Gastric disorder is essentially a problem of nutrition. How and with what to feed become questions of vital importance.

That "Ovaltine" will nourish when other forms of nourishment are badly borne or rejected by the patient is the burden of numerous medical reports received from physicians in all parts of the world.

"Ovaltine" too, is well adapted to duodenal or rectal feeding. In the latter, reports show that it is well absorbed and effective in maintaining the general health of the patient until oral feeding can be resumed.

"Ovaltine" has been extensively used in such conditions as Gastric Ulcer, Gastritis, Gastric Carcinoma, Stomach Atony, the Dyspepsias or wherever there is Nausea, Anorexia or other obstacle to normal alimentation.

OVALTINE

Supplied by druggists at 50c, 80c, $1.50 and $5.00

Samples and literature mailed to physicians upon signed request.

Does More and Better for Less

THIS Troy No. 115 Solid Head "Rapid" Washer will do its work in less time and use less of every item that enters into the washing process than any machine you can install, and its work will be better.

The hospital or institution laundry where it is in operation can be run more economically and efficiently and with greater satisfaction.

ABDOMINAL SUPPORTS TRUSSES ELASTIC HOSIERY

Post-operative, maternity and hernia cases are especially well cared for in a unique and efficient manner. For twenty-one years we have made our business a study, and by confining ourselves to these specialties have developed methods that assure relief to the patient and satisfaction to the doctor.

Every physician should secure a copy of our catalogue, which explains our business in detail. We have the largest and best equipped plant on the Pacific Coast and are the exclusive agents for the famous Drs. Smith's "Honest John" Truss, the only practical device for holding at the internal ring.

- alcoholism
- typhoid bacilli
- children and in infantile diarrhoea.

At All Druggists

95% Ethyl Alcohol

An Important Development

In the Medication of Alcohol

After lengthy research, the Mifflin Chemists have evolved a private formula which removes every drawback from the prescription of medicated alcohol.

Soothing and Odorless

Alkohol Massage, the result of the new formula, is really better than the old alcohol for external purposes. No wood alcohol, acetone, or other poisonous ingredients. Pleasant odor. Soothing, not injurious to the skin.

ALKOHOL MASSAGE

Physicians' samples gladly sent on request will show how satisfactory it is.

Mifflin Chemical Corporation

Delaware Ave. and Tasker St.

PHILADELPHIA, U. S. A.

Prevention *like this*:-

"It is certainly a pleasure to send you this renewal premium check, when I think how completely you shut up my blackmailer. I have not heard anything more from him and cannot too highly recommend your company for the prompt and efficient manner in which you handled the threat. I practiced 21 years before I struck a snag.

"Yours truly."

Defense *like this*:-

"Dear Sirs:

"We want to express our appreciation for the services rendered us in our recent case.

"We feel that the success of this case is due entirely to the wonderful defense. As medical men we followed your technique very closely and we wish to say that, in our opinion, you have a talent for this type of cases unequalled by any one.

"Very truly yours."

Indemnity *like this*:-

"The company shall indemnify the holder hereof against any judgment or loss imposed by law upon the holder hereof in any claim or suit defended by the company. Such indemnity shall be limited to Ten Thousand ($10,000) in any one claim or suit, and Thirty Thousand ($30,000) in all claims and suits arising hereunder, such indemnity being in addition to the unlimited defense."—Clause "G" of our Contract.

San Francisco Polyclinic and Post Graduate Medical College

FOUNDED 1889

Announcement of Graduate Courses

THE San Francisco Polyclinic and Post Graduate College has reorganized its teaching staff for the purpose of resuming the post graduate instruction that was interrupted by the world war. San Francisco, on account of its central location, its great hospitals and universities, offers unusual facilities for graduates in medicine to obtain opportunities for Post Graduate study.

Systematic courses in all branches of medicine and surgery are given. The next series begins September 1, 1922.

Attention is called to the two weeks' course in **operative technique.** Operations are performed by the student on the living dogs after preliminary demonstrations on the cadaver of the surgical anatomy of each operation.

Courses are also given in surgery of the Tonsils, Fractures, Orthopedics, Urology, Proctology, Opthalmology, Rhinology, Laryngology, Otology, Roentgenology, Obstetrics and Radio-therapy. All courses are practical in character and illustrated by clinical demonstrations, lantern slides, etc. A general course can also be arranged. For details, apply to

Public Health a Part of Medicine—The public is not satisfied with a service which is devoted only to the cure of maladies and the mending of injuries, but is very much alive to the advantages of the prevention of disease and the conservation of health; and he, the practitioner, should be equally alive to his opportunity to secure leadership in such movements, a leadership which is his to hold and maintain, provided he approaches the problem in a spirit of co-operation and with a "resolute will to win." Moreover, as a recent investigation has shown, when properly conducted health activities (preventive medicine) are in operation, and secure the doctor's co-operation, not only is the total number of people applying to the practitioner for treatment increased, but his work has been made simpler and more effective. Again, the establishment of a rural hospital, where its need is definitely recognized, financed and managed, as in most instances it would be, with lay aid, but open freely to the doctors of the district, and with all its facilities at his disposal, as should be the case, represents an important incentive for young graduates in medicine to go to such regions, making their start as interns within its walls. . . .

The advancement of medical effort, the improvement of medical education, the highest type of medical service in the cure of the sick and injured and in the conservation of health, the protection of medical and public interests, leadership in all the phases of medical activity and the maintenance of ethical standards—these are the agenda of our Association. With confidence we face the future—its coming events, its opportunities, its responsibilities. Let us be loyal in thought and action, steadfast in effort, united in purpose, remembering that "The one Great Light which halos all is passionate bright endeavor."—From the Address of President-Elect De Schweinitz, Journal of the A. M. A., May 27, 1922.

Placing a Premium on Unfitness—Undue solicitude for the comfort and welfare of prison inmates, incorrigible moral defectives out of prison, inveterate paupers, wastrels, and drunkards—unless it is accompanied by a rigid restriction of reproduction—can only lead to the contamination of future generations with undesirable qualities by a very great number of inferior individuals whose undesirable qualities might better perish with them.

Measures of taxation which impose an undue and excessive burden upon the mentally superior, the efficient, the successful, and the self-sufficient in order to ameliorate the living conditions of the dull-witted, incompetent, inefficient, timid, and self-indulgent, can but augment the propagation of the unfit and restrain the reproduction of the fit. Since the growth of democracy has obliterated the demarcations of social class, intermarriage of the superior with the inferior is unrestrained. This leads to the extinction of superior qualities just in the proportion in which the inferior individuals numerically exceed the superior—and this proportion is very great. Really superior individuals comprise only three or four per cent of the whole.—Colorado Medicine, April, 1922.

Colfax School for the Tuberculous

Experience has shown that Sanatorium treatment is the most efficient and most approved method of treating the tuberculous. Those patients who are able to take advantage of the superior facilities offered by sanatorium treatment should not be denied the opportunity of receiving these benefits.

The cottage colony of the Colfax School for the Tuberculous provides accommodations for patients who have not only all the advantages of the sanatorium regime and supervision but at the same time have the benefit of home cooking and surroundings. While the patient improves the other members of the family daily receive instructions relative to those things everyone should know regarding tuberculosis.

Information regarding the methods of treatment and other details of interest to the physician and his patient are given in a booklet which will be sent on request.

Armour's LABORATORY PRODUCTS

"Why Take a Chance, When You May Be Sure, in Treating Thyroid Insufficiency?"

The most recent method of treating Thyroid Insufficiency is to administer two-grain doses of **Standardized Thyroids** t.i.d. until the usual symptoms of hyperthyroidism appear; then give small doses (1-10 or 1-4 grain) to maintain balance.

The Armour Thyroid Preparations are **stable** and dependable. They are standardized for **iodine** content and run uniformly.

The Armour Thyroid Products represent all the therapeutic properties of normal Thyroid glands unimpaired, as all desiccating is done in vacuum ovens at a temperature never above 105 degrees F.

We offer Thyroid Powder and 1-10, ¼, ½, 1 and 2 grain compressed tablets.

BALTIMORE

Court Decision Relating to Physicians' Fees Under Workmen's Compensation Acts—Appellate Courts of New York, Wisconsin, and Illinois have recently rendered decisions of great importance to physicians rendering services under the provisions of Workmen's Compensation Acts.

The decisions of these courts of three different States with different laws were upon similar points, and the decisions are uniformly important and gratifying to physicians.

The point at issue was whether or not the Industrial Accident Commission had the power to fix a fee schedule for medical services that would be binding upon all physicians; and that a physician could not collect from insurance companies and carriers in accordance with a fee schedule adopted by the State Medical Society when this fee differed from that approved by the Industrial Accident Commission.

The Workmen's Compensation Acts of all of these States provide, in effect, that the "Commission shall have the power to fix the amount of fee for any person performing services under the provisions of the Act."

Mr. Justice Matchett delivered the opinion in the Illinois case. Justices Dever and McSurely concurring.

The opinion in part states:

"The theory on which our Compensation law is based is that the parties to whom it applies, the employer and his employes, must voluntarily elect to come under its provisions. It is only when they have so elected that the Act deprives the courts of their jurisdiction to enforce contractual terms between them. The manner in which they shall come under the Act is distinctly provided for, but there is no provision in the Act by which physicians may voluntarily come under its provisions. In Noer v. Jones Lumber Co. (Wis.), 175 N. W. Rep., p. 784, where a similar question arose under the Wisconsin statute, the Court said:

" 'The Working Men's Compensation Act deals exclusively with matters growing out of the relation of employer and employe: the provisions of the Act are binding upon employers and employes electing to be bound by them, and upon none others; all except employers and employes are strangers to the Act, and their usual lawful rights and remedies are unaffected by it.'

"To the same effect is National Car Co. v. Sullivan, 126 N. E. 494."

The importance and far-reaching possibilities of these decisions are very great. The principle enunciated, if wisely used, will not only restore to the medical profession some of their rights in connection with the Workmen's Compensation Act, but will furnish physicians with a formidable weapon in controlling other attempts to make health the football of politics, and the physician the hireling of the "ins" of a paternalistic government.

Subscription prices, including postage, per annum in advance: Domestic, $4.00; Canadian, $5.00.

Domestic rates include United States, Cuba, Mexico, Hawaii, Guam, Porto Rico, Canal Zone and Philippine Islands.

Acceptance for mailing at special rate of postage provided for in Section 1103, Act of October 3, 1917, authorized August 10, 1918.

SINGLE COPIES of this calendar year, 50 cents.

REMITTANCES should be made by check, draft, registered letter, money or express order. Currency should not be sent unless the letter is registered. Stamps in amounts under one dollar are acceptable. Make all checks, etc., payable to "Medical Society, State of California."

VOLUMES begin with the first of January. Subscriptions may commence at any time.

CHANGE OF ADDRESS notice should give both the old and the new address, and state whether the change is permanent or temporary. The change notice must reach us ten days in advance of the date of the issue which is to be forwarded to the new address.

WARNING: Pay no money to an agent unless he presents a letter showing authority for making collection.

ADVERTISEMENTS.

Advertising forms go to press fifteen days in advance of the date of issue. In sending in copy time must be allowed for setting up advertisements and for sending proofs. No proprietary medicines can be advertised until approved by the Council on Pharmacy and Chemistry. Advertising rates will be sent on request.

CONTRIBUTIONS.

EXCLUSIVE PUBLICATION: Articles are accepted for publication on condition that they are contributed solely to this journal.

CONTRIBUTIONS TYPEWRITTEN: Authors must have their contributions typewritten—double-spaced and with ample margins—before submitting them. The expense is small to the author—the satisfaction is great to the editor and printer. We cannot promise to return unused manuscript, but try to do so in every instance. Manuscript should not be rolled.

ILLUSTRATIONS: Half-tones and zinc etchings, if necessary to elucidate the text, will be furnished by The Journal when satisfactory photographs or drawings are supplied by the author. Each illustration, table, etc., should bear the author's name on the back. Photographs should be clear and distinct; drawings should be made in black ink on white paper. While we cannot guarantee to return used photographs and drawings, we use our best endeavors to do so after the article is published, if the word "return" is written on the back of each.

ANONYMOUS CONTRIBUTIONS, whether for publication, for information, or in the way of criticism, are consigned to the wastebasket unread.

NEWS: Our readers are requested to send us items of news of a medical nature, also marked copies of local newspapers containing matters of interest to physicians. We shall be glad to know the name of the sender in every instance.

Kindly Mention This Journal When Applying

Dr. King's Sanatorium

(THE BANNING SANATORIUM)

Banning (Riverside County) California

This well known institution (for the treatment of tuberculosis of the throat and chest) has recently been rebuilt and enlarged. The City of Banning (suffering from phthisiophobia) passed a "zoning" ordinance that forced abandonment of the former site of this sanatorium. A new site was purchased. An injunction was sought to prevent the use of the new site for sanatorium purposes. A temporary injunction was granted but, at the final hearing, this injunction was dissolved and the right to build and maintain the sanatorium was established. Many of the most prominent physicians in the state contributed testimony that enabled us to win the suit. During the progress of these suits the institution found it difficult to provide for patients demanding admission. Now, however, in its new quarters, it is prepared to accept all who apply. To physicians who are unfamiliar with our work we will gladly furnish references to other physicians (in almost every town in California) who have had patients or relatives in this institution. A circular describing conditions and containing rates will be mailed upon request. Address

DRS. KING and BRAMKAMP. BANNING, CALIFORNIA.

HAY FEVER MEMORANDA

LATE SUMMER TYPE—Patients whose hay fever develops in mid-August and continues until frost should be tested with pollens of local importance—primacy being given to the long distance wind-pollinated plants, e. g., ragweed. However, where contact is unavoidable, as on a farm, the short distance wind-pollinated plants, e. g., corn—and the insect-pollinated plants, e. g., sunflower, which are also atmospheric—cannot safely be ignored.

THE BABY CLARKE is appropriately named It is a portable gas outfit which the physician can very well take with him as part of his obstetrical equipment. There is constant and legitimate call from women patients that some of the terrors of obstetrical pain be relieved. It is the common practice now in hospitals to use gas for this purpose. THE BABY CLARKE will render the same service to the obstetrician and may be carried to the patient's home and used there or anywhere else.

The portable apparatus is automatic, and requires no attention in analgesia, also used in minor operations. Most progressive men are using Nitrous Oxid-Oxygen in their Obstetrics.

CALCREOSE

Calcium in Intestinal Tuberculosis

"The administration of calcium chlorid in tuberculous diarrhea is, we believe, based on empiricism, but of its good effects there are at present many undeniable examples. . . . We have used calcium chlorid in no sense as a curative agent, but merely as a palliative in an attempt to control the distressing symptoms of pain and diarrhea." —**P. H. Ringer** and **C. I. Minor**, Am. Rev. Tuberc., 5:876 (Jan.) 1922.

CALCREOSE (calcium creosotate) is a mixture containing in loose chemical combination approximately equal parts of creosote and lime.

CALCREOSE has the same actions and uses as creosote but is free from its untoward effects on the stomach. Creosote is used as an intestinal antiseptic.

Secretary

WE BELIEVE

THE Medical Profession will be pleased to know that for the past nine months the Sherman 10 mil. vial has been filled to contain 12½ milliliters of vaccine.

In the future this package will be known as a 12½ mil. vial and will sell at $2.00, the price of the former 10 mil. vial. This is equivalent to a price of $1.60 on a 10 mil. basis and is an increase of 25 per cent in the quantity of vaccine.

FEE SCHEDULE
(Revised May 1, 1922)

BLOOD—	
Leucocyte Counts, Differential Leucocyte counts, Red blood counts, Hemoglobin determinations	$3.00, 3.00, 3.00, 3.00 — $5.00, $5.00 — $ 8.00
Blood cultures	15.00
Blood smears for blood parasites, as malarial plasmodia	3.00
Blood group tests	5.00
Blood Chemistry (sugar, urea nitrogen, non-protein nitrogen, creatinin, uric acid, CO_2 combining power), single item	5.00
Each additional item	3.00
Wassermann tests—blood	5.00
Widal (agglutination) test	3.00
Coagulation and bleeding times	5.00
URINE—	
Urinalysis, routine	3.00
Phenolsulphonephthalein excretion	5.00
Microscopic examination for tubercle bacilli	3.00
Bacteriologic examination	5.00
STOOLS—	
Microscopic examination of stools	5.00
Examination of stools for invisible blood	3.00
Bacteriologic examination for typhoid and dysentery group	15.00
STOMACH CONTENTS—	
Chemic and microscopic examination of stomach contents	5.00
Test meal and obtaining contents for examination	5.00
SPUTUM—	
Microscopic examinations for tubercle bacilli	3.00
Pneumococcus typing with mouse method	15.00
Cultural examination	10.00
EXUDATES—	
Bacteriologic and microscopic examination of exudates	5.00
Diphtheria	5.00
Cerebro-spinal fluid examinations for syphilis (Wassermann test, cell count, globulin test)	8.00
Colloidal Gold test	5.00
Microscopic examination of smears, as for gonococci and Vincent's angina, sent to the laboratory	3.00
LUMBAR PUNCTURES (without examination of fluids)	10.00
VON PIRQUET TUBERCULIN TEST	5.00
DARK FIELD EXAMINATION for spirochaetes	10.00
TISSUES—	
Tissue examination	10.00
Pathologic consultation at operation (frozen sections when necessary)	25.00
VACCINES—BACTERIAL	10.00
WATER—	
Bacteriologic examination	15.00
MILK—	
Chemic examination	5.00
Bacterial count	5.00
ANIMAL INOCULATION for tubercle bacilli	15.00
BASAL METABOLISM DETERMINATION	15.00
BLOOD TRANSFUSION (not including cost of donors)	$100.00 to 150.00
EXAMINATION OF ANIMAL BRAINS FOR RABIES	15.00
ANTI-RABIC TREATMENT, 21 injections, including vaccine material	150.00

POST-MORTEM examinations by special arrangement.

CALIFORNIA STATE JOURNAL OF MEDICINE

RESOLUTION ON "SHEPPARD-TOWNER LAW"

"WHEREAS, The Sheppard-Towner law is a product of political expediency and is not in the interest of the public welfare, and

"WHEREAS, The Sheppard-Towner law is an imported socialistic scheme unsuited to our form of government, and

"WHEREAS, The Sheppard-Towner law unjustly and inequitably taxes the people of some of the States for the benefit of the people of other States for purposes which are lawful charges only upon the people of the said other States, and

"WHEREAS, The Sheppard-Towner law does not become operative in the various States until the States themselves have passed enabling legislation, therefore be it

"RESOLVED, That the American Medical Association disapprove the Sheppard-Towner law as a type of undesirable legislation which should be discouraged."—(*Abstract from Minutes of the Seventy-third Annual Session of the A. M. A.*)

Beautify Your Offices

A DOCTOR'S OFFICE equipped with beautiful white, washable steel furniture radiates sanitation, order and technical efficiency. Such surroundings place the Doctor in good working humor and improves his technique. But, most important of all, is the pleasing mental attitude white, steel equipment produces in the patient's mind.

The seven-piece office furniture set shown above has been designed, constructed and priced to enable the profession to discard their obsolete equipment and install modern furniture. Only the finest of materials and workmanship enter into its construction. Silver furniture steel is used—all metal trimmings are heavily plated with non-rustable nickel—the white enamel is put on in six or more coats, oven baked, and all surfaces can be scoured like a dish. This set will give constant year-in-year-out service and—

It Costs Only $154.75

We send the set on 15 days' free inspection. If it is not what we claim, we take it back, pay the freight charges both ways, and the transaction will not cost you a penny. Don't overlook this opportunity to modernize your offices at this low cost. Fill in and mail the coupon below and we will send you an illustrated booklet giving description and measurements of each piece and telling more about the terms.

HAY-FEVER

CAN BE ALLEVIATED AND IN MANY CASES PREVENTED BY EARLY TREATMENT WITH AN EFFICIENT PROPHYLACTIC. THE TREATMENT SHOULD BE STARTED SIX WEEKS IN ADVANCE OF THE ANTICIPATED ATTACK

POLLEN ANTIGENS - *Lederle*

Are prepared by extracting the dried pollen in 66 2/3 per cent glycerol and 33 1/3 per cent saturated sodium chloride solution. *This ensures their uniform stability.*

They are standardized against antipollen serum by the complement fixation method which accurately determines the amount of antigenically active pollen protein. *This ensures their antigenic activity and provides for accurate dosage.*

Pollen Antigens-Lederle are supplied to the physician in accurately measured doses, properly preserved, each dose accompanied by a vial of sterile diluent. The antigen and diluent are not mixed until just before injection, thus guarding against the loss of specific antigenic properties.

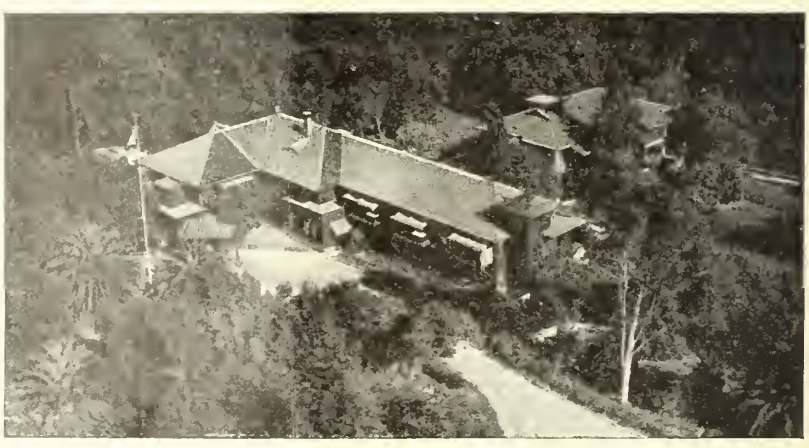
AIRPLANE VIEW OF GROUNDS

A SANITARIUM FOR THE TREATMENT OF ALL FORMS OF NERVOUS DISORDERS AND GENERAL DISEASES

SIXTEEN MILES FROM LOS ANGELES, HEART OF THE ORANGE BELT



MAIN BUILDING

LOCATION—Situated in the foothills of the Sierra Madre Mountains, just outside of the city of Pasadena, is this beautiful sanitarium. It is surrounded by a natural live-oak grove of 20 acres, with lawns and gardens, ideally adapted to rest and enjoyment. Large central building and cottages all modernly equipped. Homelike and comfortable.

Climate Ideal.
Cuisine Excellent.
Outdoor Sports and Recreation.

EQUIPMENT—Special equipment for aiding in a correct diagnosis. The Laboratory, Hydrotherapy and Electricity Departments are important adjuncts to the general Sanitarium treatment. All forms of baths are given, including the famous Nauheim.

Dairy and Poultry Plant.
Rooms With or Without Baths.
Private Bungalows With Sleeping Porches.

CLASS OF PATIENTS — All forms of nervous disorders and general diseases are treated. Special attention is paid to Gastro-Intestinal disorders and Circulatory System. No Tuberculosis, Epilepsy or Insanity received.

BOARD OF DIRECTORS.— Norman Bridge, M. D., H. C. Brainerd, M. D., W. Jarvis Barlow, M. D., F. C. E. Mattison, M. D., Stephen Smith, M. D.

HYDROPATHIC DEPARTMENT

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

COTTAGE DEPARTMENT

THE LIVERMORE SANITARIUM

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the U. S.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) $45.00 per week and upward.

ANNOUNCES

THAT ITS X-RAY DEPARTMENT IS NOW EQUIPPED

WITH A

MODERN DEEP THERAPY X-RAY APPARATUS

FOR THE

PRE- AND POST-OPERATIVE RADIATION OF DEEP MALIGNANCY

AND THE

TREATMENT OF INOPERABLE MALIGNANT CONDITIONS

This type of apparatus with its ability to produce a voltage of 280,000 volts (about twice the voltage capacity of X-ray machines hitherto available) gives an X-ray beam of enormously magnified penetrating power as compared to those previously in use.

Heavy filtration is used as an added factor in increasing the ratio of the depth to the skin dose, thus markedly decreasing the liability of injurious skin effects while as markedly increasing the effect on the deep tissues.

CALIFORNIA PRACTICE OR LOCATION WANTED—A1 graduate with 25 years experience in Greater New York City wishes to locate in California. Any physician who has an opening or wishes to retire communicate with the undersigned. Would consider a drug store in connection with practice. Available after August 1, 1922. Town of 3000 or more preferred. R. Edward Meyers, M. D., 322 Gazette Building, Reno, Nev.

Buying Power
of Our Members

There are 3842 members of the Medical Society of the State of California and readers of this Journal, located in every important city and town of this State.

This means 3842 circles of practice, which touch and influence over 1,921,000 people in the homes, industries and institutions throughout the State.

Think of the BUYING POWER of these physicians! If their average expenditure is only $1000, that amounts to $3,842,000 a year. But medical supplies bought on physicians' prescriptions, and goods purchased on their orders or recommendations for Sanitariums, Hospitals, Boards of Health, etc., would fully equal that amount—or a total of $7,500,000.

If members will give preference in all their buying to advertisers in their State Medical Journal, other advertisers will want space, and the publishers can then print a LARGER and BETTER Journal.

If you do not find advertised here the goods you want, please write the Journal. We will secure the information for you.

Ross Sanitarium

In Sunny Marin County, California

Scientific and homelike sanitarium and hospital service. 55 minutes from San Francisco. Dairy products, poultry and vegetables fresh daily from Ross Sanitarium Farm.

Resident physician. X-Ray equipment. Complete laboratory and operating room service. Any member of A. M. A. can attend his own patients here if he wishes. Ideal for convalescent, chronic and rest-cure cases of all types. Competent staff and consultants available if desired.

THE SANITARIUM WITH A PERSONALITY

Address all communications to Medical Director, Ross Sanitarium, Ross, California

CHLORETONE
the *sensible* hypnotic

THE frequency with which you find indications for the exhibition of hypnotics makes it essential that your favorite remedy in this class be broadly serviceable—produce results you can count on, and give rise to a minimum of discomfort.

That's why many of your fellow practitioners have for years relied on Chloretone.

Prescribe Chloretone in doses of 5 to 20 grains—always in capsules, because the crystals are volatile. Prescribe the larger doses in cases of delirium, convulsions, uremia, tetanus, and hydrophobia. The smaller doses are required in cases of insomnia and restlessness, and in the symptomatic treatment of epilepsy. Chloretone is especially efficacious in combating seasickness and gastric irritability.

Parke, Davis & Company

New Publications

The 1922 Catalogue.

A Booklet on the subject of Pertussis Vaccines.

Gladly sent physicians on request.

Gastric Disorders

Gastric disorder is essentially a problem of nutrition. How and with what to feed become questions of vital importance.

That "Ovaltine" will nourish when other forms of nourishment are badly borne or rejected by the patient is the burden of numerous medical reports received from physicians in all parts of the world.

"Ovaltine" too, is well adapted to duodenal or rectal feeding. In the latter, reports show that it is well absorbed and effective in maintaining the general health of the patient until oral feeding can be resumed.

"Ovaltine" has been extensively used in such conditions as Gastric Ulcer, Gastritis, Gastric Carcinoma, Stomach Atony, the Dyspepsias or wherever there is Nausea, Anorexia or other obstacle to normal alimentation.

OVALTINE

Supplied by druggists at 50c, 80c, $1.50 and $5.00

Samples and literature mailed to physicians upon signed request.

The Wander Company, 37 South Wabash Avenue, Chicago

This Machine Revolutionized Laundry Drying

THIS TROY Hot Air Dryroom Tumbler does the work of the ordinary dry room in half the time and with less expense than any other method of drying.

All you have to do is to put the goods to be dried in the cylinder and start the machine.

The Troy Hot Air Dryroom Tumbler will dry everything except collars and shirts.

Write for special circular and names of some representative users.

Resolution on Medical Education—(Abstract)—"It is further believed that the plan of some of the great foundations to require full-time clinical professorships is not wise and does not receive the support of the general profession. Your committee doubts the wisdom of making the adoption of such a plan a condition of endowment.

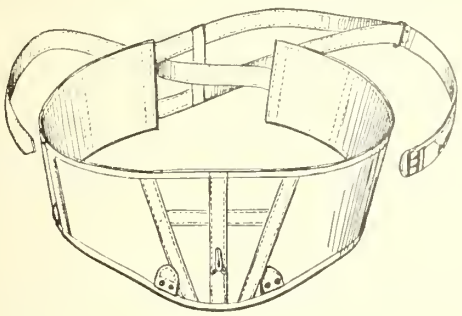
"The tendency toward premature or over-rapid specialization is deplored. The practice of entering a special field without the proper preliminary general and special training should be checked. It is urged that medical schools so revise their curriculums as to provide a thorough training for the general practice of medicine, leaving courses in the specialties for the graduate medical school.

"As a means to correct in part the faulty distribution of physicians, as between urban and rural districts, your committee subscribes to the plan of the Council for the establishment of hospitals in all communities having sufficient population in the surrounding territory to support them; these institutions are to be under the direct control of the medical profession. It, furthermore, regards the improvement of public highways as an additional aid in providing physicians for many districts which at present do not have them.

"Your committee agrees with the views of the Council that the curriculums of medical schools should be recognized so that the study of anatomy, pathology and the other fundamental sciences may be illustrative of clinical medicine and surgery, instead of treating those sciences as entirely separate from the latter. The committee believes, as does the Council, that the study of clinical cases should begin with the first year of medical training and be carried on concomitantly with the study of the fundamental sciences, so that each group will illustrate the other.

"Your committee shares the view of the Council that there are certain obstacles in the development of a medical school as the medical department of a university. It has become clear that a medical school cannot be developed along the same comparatively narrow lines as the ordinary department of science in the university. Medicine has become one of the greatest functions of modern civilization, and has an intimate, everyday contact with every individual of the community, and the proper plan of organization must recognize this fact, and be sufficiently broad to maintain this relationship between the medical school, the medical profession and the community. The functions of medicine are performed by specially trained men and women—the medical profession. Any plan for the successful development of our medical schools must receive the active and enthusiastic co-operation of the medical profession. The medical school with its teachers and its associated agencies, hospitals, dispensaries, etc., cannot be developed simply as a university affair. It has definite and important functions to perform which are vital to the community, and a sound plan of organization must be one in which all of the agencies retain their normal place and perform their normal function. It is especially important that the teachers in the clinical departments retain their usual relationship to the medical profession."—Abstract from Minutes of the Seventy-Third Annual Session of the A. M. A.

Resolution Directing a Survey of the Nursing Situation—"Your committee approves the speaker's recommendation for a survey of the nursing institutions, and recommends its reference to the Council on Medical Education and Hospitals. They, if they deem it advisable, may submit this to a sub-committee. We recommend that a report be received from this Council on the subject at the next annual session."—Abstract from Minutes of the Seventy-Third Annual Session of the A. M. A.



ABDOMINAL SUPPORTS
TRUSSES
ELASTIC HOSIERY

Post-operative, maternity and hernia cases are especially well cared for in a unique and efficient manner. For twenty-one years we have made our business a study, and by confining ourselves to these specialties have developed methods that assure relief to the patient and satisfaction to the doctor.

Every physician should secure a copy of our catalogue, which explains our business in detail. We have the largest and best equipped plant on the Pacific Coast and are the exclusive agents for the famous Drs. Smith's "Honest John" Truss, the only practical device for holding at the internal ring.

TREATMENT TABLE

95% Ethyl Alcohol

An Important Development

In the Medication of Alcohol

After lengthy research, the Mifflin Chemists have evolved a private formula which removes every drawback from the prescription of medicated alcohol.

Soothing and Odorless

Alkohol Massage, the result of the new formula, is really better than the old alcohol for external purposes. No wood alcohol, acetone, or other poisonous ingredients. Pleasant odor. Soothing, not injurious to the skin.

ALKOHOL MASSAGE

Physicians' samples gladly sent on request will show how satisfactory it is.

Useless to Remain--- Dangerous to Move---

At least it would appear that way until consideration is given to the fact that the Doctor holds a Medical Protective Contract.

"The Medical Protective Company,
Fort Wayne, Indiana,

"Dear Sirs:

"I have understood that the other side could hold my office equipment, drugs, etc., and prevent me from moving same out of the office or town to another location. This also affects even a checking account in bank, local or otherwise.

"I will be here if needed, but I have planned on changing my location long before this case came up, but I wanted to get my collections in first. Now, if I should change locations and they try to hold my belongings, what is best to do as a preventive, etc.?

"Yours very truly,
"_____"

In many States there is no exemption against a judgment in a malpractice suit, and in other States practically none. A suit for malpractice sounds in tort and a judgment can be levied against everything you own, or may acquire in the future. You must pay or quit, or both, if you do not have protection.

For Medical Protective Service
Have a Medical Protective Contract

San Francisco Polyclinic and Post Graduate Medical College

FOUNDED 1889

Announcement of Graduate Courses

THE San Francisco Polyclinic and Post Graduate College has reorganized its teaching staff for the purpose of resuming the post graduate instruction that was interrupted by the world war. San Francisco, on account of its central location, its great hospitals and universities, offers unusual facilities for graduates in medicine to obtain opportunities for Post Graduate study.

Systematic courses in all branches of medicine and surgery are given. The next series begins September 1, 1922.

Attention is called to the two weeks' course in **operative technique.** Operations are performed by the student on the living dogs after preliminary demonstrations on the cadaver of the surgical anatomy of each operation.

Courses are also given in surgery of the Tonsils, Fractures, Orthopedics, Urology, Proctology, Opthalmology, Rhinology, Laryngology, Otology, Roentgenology, Obstetrics and Radio-therapy. All courses are practical in character and illustrated by clinical demonstrations, lantern slides, etc. A general course can also be arranged. For details, apply to

At All Druggists

Colfax School for the Tuberculous

Experience has shown that Sanatorium treatment is the most efficient and most approved method of treating the tuberculous. Those patients who are able to take advantage of the superior facilities offered by sanatorium treatment should not be denied the opportunity of receiving these benefits.

The cottage colony of the Colfax School for the Tuberculous provides accommodations for patients who have not only all the advantages of the sanatorium regime and supervision but at the same time have the benefit of home cooking and surroundings. While the patient improves the other members of the family daily receive instructions relative to those things everyone should know regarding tuberculosis.

Information regarding the methods of treatment and other details of interest to the physician and his patient are given in a booklet which will be sent on request.

An Outfit for Determining Variations in

The Hydrogen-ion Concentration of the Blood

The apparatus includes a series of standard color solution tubes—PH range 6.6 to 8.6—and is quite useful in diagnosing acidosis. It is also being used quite extensively in determining the concentrations of culture media.

The PH range—6.6 to 8.6—permits the use of this apparatus for determining the hydrogen-ion concentrations, within practical limits, of

INTRAVENOUS SOLUTIONS

As indicated in the papers of Williams and Swett, "The Journal," A. M. A., April 8, 1922, p. 1024, and Mellon, ibid, p. 1026, it is dangerous to inject relatively large volumes of solutions into the blood stream which have a hydrogen-ion concentration differing appreciably from normal blood, approximately, PH 7.4. Solutions outside of the PH range—6.6 to 8.6—would, of course, be unsafe to use.

Hynson, Westcott & Dunning

BALTIMORE, MD.

Resolution on Volstead Act.—Abstract from Minutes of the Seventy-Third Annual Session of the A. M. A.:

"Whereas, The medical profession has been subjected to criticism and unfavorable comment because of present conditions associated with the enforcement of the Volstead Law, and

"Whereas, The results of a referendum conducted by the Journal of the American Medical Association, covering 54,000 physicians, indicates that 51 per cent of physicians consider whisky 'necessary' in the practice of medicine, and

"Whereas, The dosage, method, frequency and duration of administration of this drug in any given case is a problem of scientific therapeutics and is not to be determined by legal or arbitrary dictum, and

"Whereas, The experience of physicians, as reported in the Journal, indicates that the present method of control, limitation of quantity and frequency of administration, licensure and supply of a satisfactory product constitutes a serious interference with the practice of medicine by those physicians who are convinced of the value of alcohol in medical practice, therefore be it

"Resolved, That the House of Delegates of the American Medical Association, in convention assembled, representing a membership of over 89,000 physicians, appeals to the Secretary of the Treasury and to the Congress of the United States for relief from the present unsatisfactory conditions, and recommends that provisions be made for supplying bonded whisky, for **medicinal use only,** at a fixed retail price to be established by the Government."

WANTED — To buy established practice. Give particulars. Address F. W. D., care California State Journal of Medicine.

Medical Ethics or the Application of the Golden Rule to Physicians—"Many physicians, it is to be feared, have quite unconsciously tolerated on the part of groups and institutions with which they are connected acts which they would not for a moment have considered if they had felt that they individually were responsible for them.. It has always been recognized, for instance, that "solicitation of patients" is unprofessional, and that a physician cannot ethically engage in such solicitation. Justice and fairness demand that the practice be not indulged in by physicians through groups or institutions with which they may be connected, any more than it would be indulged in by such physicians acting in their individuaul capacities. These considerations led the House of Delegates at the last annual session in St. Louis to incorporate in the 'Principles of Ethics' the following, so that there might be no douubt as to the duty of groups and institutions or of the physicians connected with them:

> Sec. 4. Solicitation of patients by physicians as individuals, or collectively in groups by whatsoever name these be called, or by institutions or organizations, whether by circulars or advertisements, or by personal communications, is unprofessional. This does not prohibit ethical institutions from a legitimate advertisement of location, physical surroundings and special class—if any—of patients accommodated.

"As may be noted, it is recognized that 'institutions' which provide means for treating the sick and which have certain physical attributes which can properly be announced may call attention to these facilities. But groups of physicians associated for any reason, in group clinics or other institutions, should conform to the restrictions governing the individual physician. For professional and quasi-professional acts committed by such groups or institutions, the physicians connected therewith must hold themselves accountable."—(Journal A. M. A., July 8, 1922.)

Hospitals and Medical Education.—"A glance at the conditions of medical education in America would make it seem clear that, from now on, there will be an ever-increasing demand for medical teaching in the non-university hospitals. For, in the first place, undergraduate students can profit by certain educational opportunities that the extramural (non-university) hospitals can make available to them and which the intra-mural (university) clinics cannot offer. In the second place, graduate clinical education is almost wholly unprovided for by the university hospitals and it seems likely that for a long time ahead it must be chiefly carried on within non-university hospitals. And, in the third place, those who are in charge of non-university hospitals are coming rapidly to a realization of a very important fact, namely, that medical teaching and research are essential concomitants of all higher forms of medical practice, even in institutions whose primary function is not in the ordinary sense 'educational.' * * * *

"It should be clear then that the facilities for graduate medical education must speedily be augmented in this country. The opportunities in our larger cities, especially New York, Philadelphia, Boston, Baltimore, Chicago, St. Louis, New Orleans and San Francisco are already better than they were five years ago, and institutions in some of the smaller places, notably Rochester, Minn., are opening their doors to the graduate student. Still, a more systematic organization of the materials and forces available for graduate instruction is an imperative need. A vast field here lies open for cultivation especially by those that are in control of our non-university hospitals."—Lewellyn F. Barker, The Modern Hospital, June, 1922.

Neuropsychiatry Problems — "In many juvenile and criminal courts the opinions of the psychiatric adviser, in determining the fate of the accused, are of as great importance as or of greater importance than the paragraphs of law concerned. Among educators we find the same demand. In the grade schools, high schools and colleges alike, teachers are asking for aid in dealing with problems in connection with behavior or refractoriness to certain studies or activities on the part of pupils.

"Shall this aid be given by the psychologist without medical training or by the medical man possessing knowledge of normal and abnormal psychology? Experience has shown again and again the importance of the medical point of view in connection with these problems, and it is our duty to meet these demands for aid and not pass them by default to the non-medical psychologists. Let me warn you that the medical profession has no time to lose before facing these issues. One has merely to observe the tables of contents of popular magazines and the subjects of lectures before clubs and public and private gatherings of all kinds to appreciate the extent of the invasion of the field of psychopathology by all kinds of lay psychanalysts and psychologists, some of them well trained and well meaning, others dangerously contaminated by occultism, obscurantism, commercialism, or by all of these."—Peter Bassoe, Jour. A. M. A., June 17, 1922.

The Pacific Northwest Medical Assn.—This association held its first meeting in Spokane July 6, 7 and 8, and had an attendance of five hundred from the territory taking in Montana, Idaho, Utah, Washington, Oregon and British Columbia.

The headquarters of the convention were in the lobby of the Davenport Hotel, which was crowded with those in attendance, among whom were notable national medical figures: Frank Billings, Henry Christian, Jos. C. Bloodgood, Walter B. Cannon and E. C. Rosenow of Rochester, Minn.; Arthur D. Dunn of Omaha, Wm. Engelbach of St. Louis, Robt. Milwee of Dallas, Tex.; W. J. Terry of San Francisco, F. M. Pottenger of Monrovia, Cal.; John Butler of Minneapolis, L. J. Hirschman of Detroit, Mich.; A. W. Adson of Rochester, and Frank E. Sampson of Creston, Iowa.

The meeting was a decided success in every way, the attendance large, representative, and included some twenty-five men from California.

A permanent organization was made, J. Earl Else was elected President, Homer D. Dudley of Seattle, President-Elect, A. S. Monroe of Vancouver, B. C., Vice-President, Jos. Tyree of Salt Lake City, Second Vice-President; F. Epplen of Spokane, Secretary-Treasurer.

Delegates were elected from Montana, Utah, Idaho, Oregon, Washington, British Columbia, Alberta and Saskatchewan.

The next session will be held in Seattle in 1923.

Dr. King's Sanatorium

(THE BANNING SANATORIUM)

Banning (Riverside County) California

This well known institution (for the treatment of tuberculosis of the throat and chest) has recently been rebuilt and enlarged. The City of Banning (suffering from phthisiophobia) passed a "zoning" ordinance that forced abandonment of the former site of this sanatorium. A new site was purchased. An injunction was sought to prevent the use of the new site for sanatorium purposes. A temporary injunction was granted but, at the final hearing, this injunction was dissolved and the right to build and maintain the sanatorium was established. Many of the most prominent physicians in the state contributed testimony that enabled us to win the suit. During the progress of these suits the institution found it difficult to provide for patients demanding admission. Now, however, in its new quarters, it is prepared to accept all who apply. To physicians who are unfamiliar with our work we will gladly furnish references to other physicians (in almost every town in California) who have had patients or relatives in this institution. A circular describing conditions and containing rates will be mailed upon request. Address

DRS. KING and BRAMKAMP. BANNING, CALIFORNIA.

HAY FEVER MEMORANDA

LATE SUMMER TYPE—Patients whose hay fever develops in mid-August and continues until frost should be tested with pollens of local importance—primacy being given to the long distance wind-pollinated plants, e. g., ragweed. However, where contact is unavoidable, as on a farm, the short distance wind-pollinated plants, e. g., corn—and the insect-pollinated plants, e. g., sunflower, which are also atmospheric—cannot safely be ignored.

ARLCO-POLLEN EXTRACTS

RADIUM
AND
ONCOLOGIC INSTITUTE

1151 WEST SIXTH STREET
LOS ANGELES

A THOROUGHLY EQUIPPED INSTITUTION affording unexcelled facilities for the scientific administration of Radium Therapy and the study and treatment of Neoplastic diseases.

THE NEW AND MODERN FIREPROOF BUILDING contains private rooms for bed and ambulatory cases, completely equipped examination and treatment rooms, Roentgen Ray, clinical and research laboratories.

THE RADIUM LABORATORY, in addition to a large and adequate quantity of Radium, is equipped with a Duane emanation apparatus and all necessary appliances, affording the most modern and complete facilities for Radium Therapy.

THIS INSTITUTION, substantially endowed, is in its equipment and capacity equal to any other in this country, and is the largest and most complete in the United States, devoted exclusively to this work.

WE DESIRE TO CONFER and cooperate with the medical profession regarding the use of Radium in appropriate cases.

THE BABY CLARKE is appropriately named It is a portable gas outfit which the physician can very well take with him as part of his obstetrical equipment. There is constant and legitimate call from women patients that some of the terrors of obstetrical pain be relieved. It is the common practice now in hospitals to use gas for this purpose. THE BABY CLARKE will render the same service to the obstetrician and may be carried to the patient's home and used there or anywhere else.

The portable apparatus is automatic, and requires no attention in analgesia, also used in minor operations. Most progressive men are using Nitrous Oxid-Oxygen in their Obstetrics.

Shall Politics, Sentiment or Education be the Basis for the Practice of Medicine and Public Health?—"At present there is an army of human parasites who are seeking to get on the payroll of the State or Government and who find the shortest and easiest route to accomplish this end is to inaugurate social welfare movements and propaganda intended to create new positions and that will give them supervision of the health welfare of the people.

Medical men spend years in preparing for the practice of medicine, and it is ridiculous to presume that after a man has spent twenty thousand dollars in money and devoted the time up to twenty-eight years of age to prepare himself for the practice of medicine that the knowledge he would acquire in his studies and clinical training would be inferior to some social uplifter's medical education."—Illinois Medical Journal, June, 1922.

Resolution on Periodic Medical Examinations.—"Whereas, The need and value of periodic medical examination of persons supposedly in health are increasingly appreciated by the public, it is recommended by the Council on Health and Public Instruction that the House of Delegates authorize the Council to prepare suitable forms for such examinations and to publish them in the Journal of the American Medical Association; and that the county medical societies be encouraged to make public declaration that their members are prepared and ready to conduct such examinations, it being understood that the indigent only shall be examined free of charge and that all others are expected to pay for such examinations."—Abstract from Minutes of the Seventy-Third Annual Session of the A. M. A.

Gland Transplantations—Transplantations of glands appear to be becoming the favorite indoor sport of millionaires as well as of certain physicians, some of whom are deficient in standing among their colleagues. Unfortunately for the success of this scheme, publicity has been breaking a little bit too early, and only the initiated know the end results to some of these patients. In California the usual publicity attendant upon this operation performed by distinguished (?) surgeons brought here from other states has been held in abeyance while some of the patients are trying to get well in hospitals.

Some Features of Medical Education—"In very early times students of medicine learned the art through a period apprenticeship. With the creation of medical schools most of the teaching was for a long period by means of lectures, and later clinical exercises came into general use in supplementing theory by the recital of fact. The accepted methods of today involve a form of hospital apprenticeship supplementary to four years' medicine school work under the title of house officer or interne. This interne service has become an essential feature of medical education and is practically universal with ambitious and well-qualified students. Hospitals have become, in a large sense, teaching institutions, because it has been found that the teaching of doctors and nurses is an essential part of hospital service. Except in the cases of a few hospitals maintained as private enterprises, the public has a right to demand that in addition to giving the best possible service to the patients, physicians and nurses should be trained so that the benefits of such institutions should be extended beyond their walls and reach all who later come under the care of those educated therein."—(Boston Medical and Surgical Journal, June 22, 1922.)

THE KROMAYER LAMP

Consider—

that the Kromayer lamp enjoys the distinction for highest intensity of Ultra-Violet radiation and the most practical means for administering treatment of many conditions.

The effective results obtained with its use over a period of ten years has been the stimulant for our scientific research work that has resulted in bringing the lamp to its present high state of efficiency.

It is chosen as the most desirable method of applying actinic rays to Lupus, Naevus, Acne, Psoriasis, Eczema, Ulcers and Wounds; to specific or non-specific orificial inflammatory conditions such as Tubercular Laryngitis, Rectal Fistulae, Otitis Media, Frontal Sinus Infections, Ozena and a number of gynecological conditions.

CALIFORNIA STATE JOURNAL OF MEDICINE

RESOLUTION ON MEDICAL ETHICS

"SOLICITATION of patients by physicians as individuals, or collectively in groups by whatsoever name these may be called, or by institutions or organizations, whether by circulars or advertisements, or by personal communications, is unprofessional. That does not prohibit ethical institutions from a legitimate advertisement of location, physical surroundings and special class—if any—of patients accomodated. It is equally unprofessional to procure patients by indirection through solicitors or agents of any kind, or by indirect advertisement, or by furnishing or inspiring newspaper or magazine comments concerning cases in which the physician has been or is concerned. All other like self-laudations defy the traditions and lower the tone of any profession, and so are intolerable. The most worthy and effective advertisement possible, even for a young physician, and especially with his brother physician, is the establishment of a well-merited reputation for professional ability and fidelity. This cannot be forced, but must be the outcome of character and conduct. The publication or circulation of ordinary simple business cards, being a matter of personal taste or local custom, and sometimes of convenience, is not per se improper. As implied, it is unprofessional to disregard local customs and offend recognized ideals in publishing or circulating such cards.

"It is unprofessional to promote radical cures; to boast of cures and secret methods of treatment or remedies; to exhibit certificates of skill or of success in the treatment of disease; or to employ any methods to gain the attention of the public for the purpo e of obtaining patients."—(*Abstract from Minutes of the Seventy-third Annual Session of the A. Beautify Your Offices

A DOCTOR'S OFFICE equipped with beautiful white, washable steel furniture radiates sanitation, order and technical efficiency. Such surroundings place the Doctor in good working humor and improves his technique. But, most important of all, is the pleasing mental attitude white, steel equipment produces in the patient's mind.

The seven-piece office furniture set shown above has been designed, constructed and priced to enable the profession to discard their obsolete equipment and install modern furniture. Only the finest of materials and workmanship enter into its construction. Silver furniture steel is used—all metal trimmings are heavily plated with non-rustable nickel—the white enamel is put on in six or more coats, oven baked, and all surfaces can be scoured like a dish. This set will give constant year-in-year-out service and—

It Costs Only $154.75

We send the set on 15 days' free inspection. If it is not what we claim, we take it back, pay the freight charges both ways, and the transaction will not cost you a penny. Don't overlook this opportunity to modernize your offices at this low cost. Fill in and mail the coupon below and we will send you an illustrated booklet giving description and measurements of each piece and telling more about the terms.

HYDROPATHIC DEPARTMENT

COTTAGE DEPARTMENT

THE LIVERMORE SANITARIUM

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the U. S.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) $45.00 per week and upward.

ANNOUNCES

THAT ITS X-RAY DEPARTMENT IS NOW EQUIPPED

WITH A

MODERN DEEP THERAPY X-RAY APPARATUS

FOR THE

PRE- AND POST-OPERATIVE RADIATION OF DEEP MALIGNANCY

AND THE

TREATMENT OF INOPERABLE MALIGNANT CONDITIONS

This type of apparatus with its ability to produce a voltage of 280,000 volts (about twice the voltage capacity of X-ray machines hitherto available) gives an X-ray beam of enormously magnified penetrating power as compared to those previously in use.

Heavy filtration is used as an added factor in increasing the ratio of the depth to the skin dose, thus markedly decreasing the liability of injurious skin effects while as markedly increasing the effect on the deep tissues.

CORRESPONDENCE AND INSPECTION BY THE PROFESSION IS INVITED

CALIFORNIA PRACTICE OR LOCATION WANTED—A1 graduate with 25 years experience in Greater New York City wishes to locate in California. Any physician who has an opening or wishes to retire communicate with the undersigned. Would consider a drug store in connection with practice. Available after August 1, 1922. Town of 3000 or more preferred. R. Edward Meyers, M. D., 322 Gazette Building, Reno, Nev.

Buying Power
of Our Members

There are 3842 members of the Medical Society of the State of California and readers of this Journal, located in every important city and town of this State.

This means 3842 circles of practice, which touch and influence over 1,921,000 people in the homes, industries and institutions throughout the State.

Think of the BUYING POWER of these physicians! If their average expenditure is only $1000, that amounts to $3,842,000 a year. But medical supplies bought on physicians' prescriptions, and goods purchased on their orders or recommendations for Sanitariums, Hospitals, Boards of Health, etc., would fully equal that amount—or a total of $7,500,000.

If members will give preference in all their buying to advertisers in their State Medical Journal, other advertisers will want space, and the publishers can then print a LARGER and BETTER Journal.

If you do not find advertised here the goods you want, please write the Journal. We will secure the information for you.

Immunization against Diphtheria

DIPHTHERIA is a definitely preventable disease. Accumulated evidence shows that practically all children can be protected by immunization with a *properly prepared* Toxin-Antitoxin mixture.

Such immunity lasts for years.

General immunization in the pre-school period with Toxin-Antitoxin would practically wipe out diphtheria.

The production of the highest degree of immunity depends on the use of an accurately balanced mixture. Over-neutralization lowers its potency. Under-neutralization undermines its safety.

Toxin-Antitoxin, P. D. & Co., is properly balanced to insure the highest immunizing effect consistent with safety.

"DIPHTHERIA IMMUNIZATION," a reprint, sent on request. Write nearest branch: Detroit, New York, Chicago, Kansas City, Baltimore, New Orleans, St. Louis, Minneapolis, or Seattle.

Parke, Davis & Company

Gastric Disorders

Gastric disorder is essentially a problem of nutrition. How and with what to feed become questions of vital importance.

That "Ovaltine" will nourish when other forms of nourishment are badly borne or rejected by the patient is the burden of numerous medical reports received from physicians in all parts of the world.

"Ovaltine" too, is well adapted to duodenal or rectal feeding. In the latter, reports show that it is well absorbed and effective in maintaining the general health of the patient until oral feeding can be resumed.

"Ovaltine" has been extensively used in such conditions as Gastric Ulcer, Gastritis, Gastric Carcinoma, Stomach Atony, the Dyspepsias or wherever there is Nausea, Anorexia or other obstacle to normal alimentation.

OVALTINE

Supplied by druggists at 50c, 80c, $1.50 and $5.00

Samples and literature mailed to physicians upon signed request.

The Wander Company, 37 South Wabash Avenue, Chicago

Ready for Use!

A scientifically prepared and accurately alkalinized solution of Arsphenamine Squibb, prepared according to the process of Dr. Otto Lowy.

Solution of Arsphenamine Squibb

Not a substitute for, but a potent solution of Arsphenamine, eliminating the dangers of oxidation and improper alkalinization; avoiding the necessity for costly apparatus and reagents; and obviating the loss of time spent in preparing solutions extemporaneously.

Prepared under license of the U. S. Public-Health Service and accepted by the Council on Pharmacy and Chemistry, A. M. A. In 80 Cc and 120 Cc ampuls with all attachments necessary to provide for administration with the same ease as a serum or antitoxin.

IF YOUR DRUGGIST CANNOT SUPPLY YOU, ADVISE US. WE WILL MAIL DIRECT TO YOU AT ONCE AND ARRANGE WITH OUR NEAREST DISTRIBUTOR.

MIFFLIN ALKOHOL MASSAGE

In a Battle of Wits—

The Medical Protective Co.,
Fort Wayne, Ind.
Gentlemen:

We began the trial of the case last Monday and finished at 10 o'clock Thursday morning. It was a hotly contested case. There was a bitter feeling but we managed to win.

Respectfully.

—o—

The Medical Protective Co.,
Fort Wayne, Ind.
Gentlemen:

The trial of the case lasted ten days. The indications are that the case will never be tried again, as the disagreement amounts to a verdict for the defendant.

Yours truly.

—o—

Professional Protection is not merely an insurance policy; it is essentially skill and experience in the defense of the suit.

—o—

Why wouldn't specialized service win in a battle of wits lasting a week or ten days or any other time?

—o—

Originators of Malpractice Insurance; over 23 years in doing one thing right; successfully handled over 14,000 claims and suits.

—o—

San Francisco Polyclinic and Post Graduate Medical College

FOUNDED 1889

Announcement of Graduate Courses

THE San Francisco Polyclinic and Post Graduate College has reorganized its teaching staff for the purpose of resuming the post graduate instruction that was interrupted by the world war. San Francisco, on account of its central location, its great hospitals and universities, offers unusual facilities for graduates in medicine to obtain opportunities for Post Graduate study.

Systematic courses in all branches of medicine and surgery are given. The next series begins September 1, 1922.

Attention is called to the two weeks' course in **operative technique.** Operations are performed by the student on the living dogs after preliminary demonstrations on the cadaver of the surgical anatomy of each operation.

Courses are also given in surgery of the Tonsils, Fractures, Orthopedics, Urology, Proctology, Opthalmology, Rhinology, Laryngology, Otology, Roentgenology, Obstetrics and Radio-therapy. All courses are practical in character and illustrated by clinical demonstrations, lantern slides, etc. A general course can also be arranged. For details, apply to

H. A. L. RYFKOGEL, M. D., Dean.

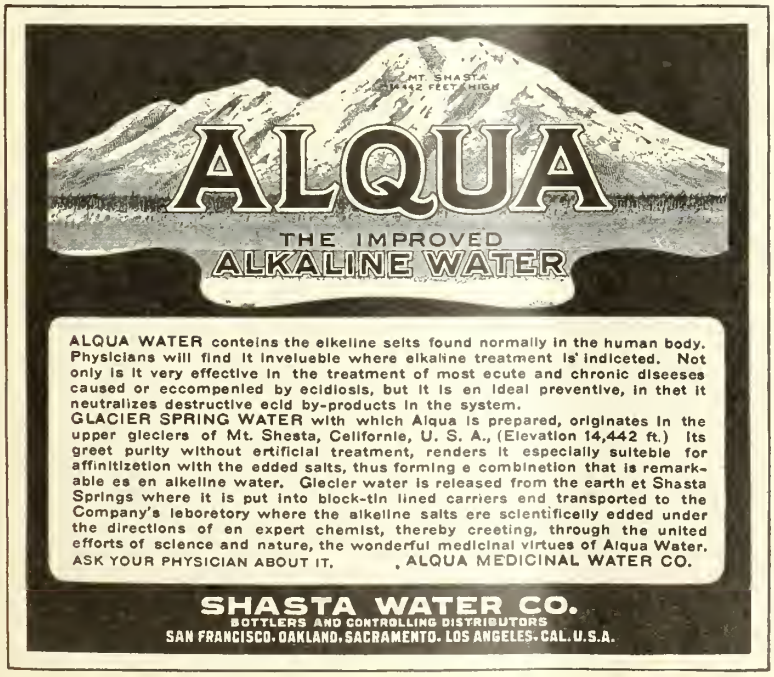
Large clinical experience conducted by clinicians of note has established the superior efficiency of ALQUA in overcoming the disagreeable and dangerous symptoms of Acidosis in—



- pre- and post-operative conditions
- pre- and post-partum conditions
- infectious diseases
- hyperacid stomach conditions
- headache, due to high acidity
- headache, due to brain oedema
- skin conditions
- genito-urinary infection
- edema—local or general nephritis
- diabetes
- asthma and hay-fever
- arterio-sclerosis
- clyclic vomiting
- alcoholism
- typhoid bacilli
- children and in infantile diarrhoea.

At All Druggists

Colfax School for the Tuberculous

Experience has shown that Sanatorium treatment is the most efficient and most approved method of treating the tuberculous. Those patients who are able to take advantage of the superior facilities offered by sanatorium treatment should not be denied the opportunity of receiving these benefits.

The cottage colony of the Colfax School for the Tuberculous provides accommodations for patients who have not only all the advantages of the sanatorium regime and supervision but at the same time have the benefit of home cooking and surroundings. While the patient improves the other members of the family daily receive instructions relative to those things everyone should know regarding tuberculosis.

Information regarding the methods of treatment and other details of interest to the physician and his patient are given in a booklet which will be sent on request.

Address all communications to

Medical Education for Teachers, Nurses and Social Workers—The Weekly Bulletin of the California State Board of Health of June 24, 1922, contains the medical and public health curriculum for teachers, nurses and social workers, to be carried out as part of the State Teachers' College program now in session. Two days of this course of instruction are devoted to preventable diseases; nine days to the principal communicable diseases, including those due to bacteria as well as those due to animal parasites; four days are devoted to the biological and social aspect of disease; six days to nutrition; four days to psychology and mental diseases of childhood; four days to public health education; and additional time to the function and objects of State, local and private welfare agencies. A number of prominent physicians are assisting the educational authorities in the carrying out of this work.

Banning (Riverside County) California

This well known institution (for the treatment of tuberculosis of the throat and chest) has recently been rebuilt and enlarged. The City of Banning (suffering from phthisiophobia) passed a "zoning" ordinance that forced abandonment of the former site of this sanatorium. A new site was purchased. An injunction was sought to prevent the use of the new site for sanatorium purposes. A temporary injunction was granted but, at the final hearing, this injunction was dissolved and the right to build and maintain the sanatorium was established. Many of the most prominent physicians in the state contributed testimony that enabled us to win the suit. During the progress of these suits the institution found it difficult to provide for patients demanding admission. Now, however, in its new quarters, it is prepared to accept all who apply. To physicians who are unfamiliar with our work we will gladly furnish references to other physicians (in almost every town in California) who have had patients or relatives in this institution. A circular describing conditions and containing rates will be mailed upon request. Address

DRS. KING and BRAMKAMP. BANNING, CALIFORNIA.

DIRECTLY and INDIRECTLY

Liquid Peptonoids

IS AN IMPORTANT NUTRITIONAL AID IN THE SICK ROOM

DIRECTLY

BECAUSE it is acceptable when all other food is rejected *and* offers immediately available nitrogen *and* calories — in sufficient amounts to be *of* real importance in emergency feeding—THEREBY saving tissue waste *and* preventing collapse.

INDIRECTLY

BECAUSE it sets the digestive pendulum in motion, kindles the appetite *and* creates food tolerance — THUS speeding the moment when more substantial nourishment may be added to the dietary.

Also DRY PEPTONOIDS (Soluble). 40% Protein—51.5% Carbohydrate.

THE ARLINGTON CHEMICAL COMPANY

YONKERS, N. Y.

RADIUM
AND
ONCOLOGIC INSTITUTE

1151 WEST SIXTH STREET
LOS ANGELES

A THOROUGHLY EQUIPPED INSTITUTION affording unexcelled facilities for the scientific administration of Radium Therapy and the study and treatment of Neoplastic diseases.

THE NEW AND MODERN FIREPROOF BUILDING contains private rooms for bed and ambulatory cases, completely equipped examination and treatment rooms, Roentgen Ray, clinical and research laboratories.

THE RADIUM LABORATORY, in addition to a large and adequate quantity of Radium, is equipped with a Duane emanation apparatus and all necessary appliances, affording the most modern and complete facilities for Radium Therapy.

THIS INSTITUTION, substantially endowed, is in its equipment and capacity equal to any other in this country, and is the largest and most complete in the United States, devoted exclusively to this work.

WE DESIRE TO CONFER and cooperate with the medical profession regarding the use of Radium in appropriate cases.

For consultation and detailed information, address

REX DUNCAN, M.D.
Medical Director

Founded 1876

THE house of E. H. Rollins & Sons, Investment Securities, was founded in 1876 and its first offices were at Concord, New Hampshire, and Denver, Colorado. It was not very many years later that the main office was transferred from Concord to Boston, where the central force of the institution still remains.

Branches, known as major offices, have since been established in New York, Chicago, San Francisco and Los Angeles, with smaller offices in many cities, giving the institution a broad scope and enabling it to come in close touch with investors and the investment situation in practically every section of the United States.

If our experience in so long a period of years will be helpful to you in your selection of desirable bonds for investment or if we can serve you by opinion or suggestion we trust you will not hesitate to call upon us.

Radium. *Physicians Attention!*

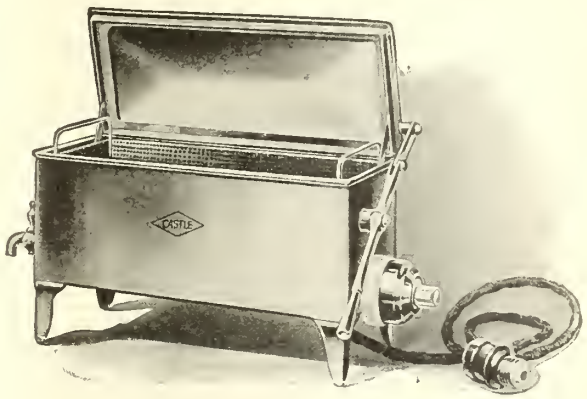
The Burnett Sanitarium is in a position to furnish emanation on demand of all physicians or surgeons desiring same, being equipped with a first-class emanation outfit. All emanations scientifically measured.

ADDRESS:

Burnett Sanitarium Company : Fresno, California

YOUR instruments cost more than your Sterilizer. Protect them with this Castle Outfit. The cut-off works before the water is all gone.

CASTLE



This No. 416 is standard for all uses. Send this Adv. to your dealer asking for full data.

WILMOT CASTLE COMPANY

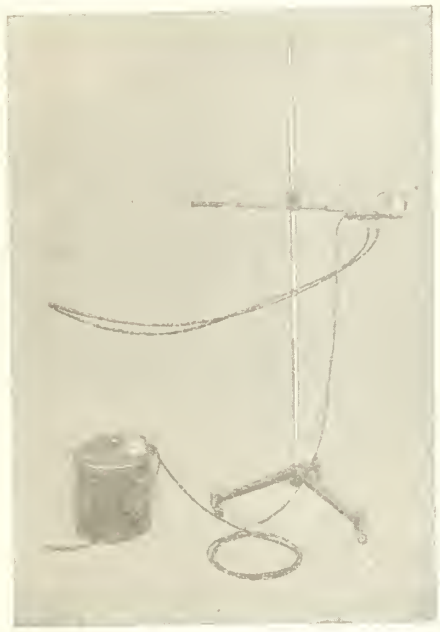
CHARLES A. MILLS, Representative SHELDON BUILDING, SAN FRANCISCO

FOR SALE—Bargain in Oakland—doctor's office and residence, on a corner and carline. Hardwood floors, furnace, large living room. Office up-to-date, treatment room in white; X-ray room. Good neighborhood practice, large area to draw from. Address F. D., care of State Journal.

Medical Women's International Association—The second meeting of the Medical Women's International Association will be held at Geneva, Switzerland, from the fourth to the seventh of September, 1922. Each society of medical women is invited to send one eligible delegate, and an additional delegate for every hundred members. Interesting reports will be read by medical women from different countries, and the constitution of the organization will probably be revised in accordance with the provisions under which it was adopted. Clinics in the different European cities may be visited en route. The attractions of travel in Europe are great this year. Practically all countries are accessible and the Passion Play will be on at Oberammergau during the entire summer.—Martha Welpton, M. D., Corresponding Secretary, First National Bank Bldg., San Diego.

FOR SALE—$6,000 buys one of the finest locations in Northern California. Lot located on main street of town, consisting of 150 feet front by 100 feet deep, with fine residence and office. Finest agricultural section in State. 100% collections. Competent surgeon can work into a good paying practice right away. Two other physicians in town—competition just right. Modern 14-bed hospital, with up-to-date X-ray laboratory in town. Buyer must be able to handle $1,000 worth of stock in hospital. To the man who wishes to get away from the heat and locate in the cool, bracing climate of Northern California, this is an opportunity of a lifetime. Address F. M., care of State Journal.

WANTED—Position with group in a California city. Specialty: Eye, Ear, Nose and Throat. Have had two years' training in Europe, just returning. Graduate of a California medical college; have California license. Address Dr. O. E. G., Box 176, Ames, Iowa.



THE KROMAYER LAMP

Consider—

that the Kromayer lamp enjoys the distinction for highest intensity of Ultra-Violet radiation and the most practical means for administering treatment of many conditions.

The effective results obtained with its use over a period of ten years has been the stimulant for our scientific research work that has resulted in bringing the lamp to its present high state of efficiency.

It is chosen as the most desirable method of applying actinic rays to Lupus, Naevus, Acne, Psoriasis, Eczema, Ulcers and Wounds; to specific or non-specific orificial inflammatory conditions such as Tubercular Laryngitis, Rectal Fistulae, Otitis Media, Frontal Sinus Infections, Ozena and a number of gynecological conditions.

WANTED—Assistantship to Obstetrician in San Francisco. Age 31, married. Graduate, 1916, New York A-1 school. Internships Bellevue and Jewish Maternity Hospital, New York City. General practice four years. Address Dr. X, care State Journal.

WANTED—Assistantship to San Francisco Surgeon. Age 31, married. Graduate 1916. Internships St. Vincent's, Bellevue, St. Mary's, St. Laurence Hospitals, New York. General practice four years. Address Dr. X, care of State Journal.

OFFICES FOR RENT IN OAKLAND; excellent central location; residence building renovated for offices. Address Dr. F. M. S., California State Journal of Medicine.

Yeast Preparations—The Council on Pharmacy and Chemistry of the A. M. A. has published an interesting report upon this subject (Journal A. M. A., July 8, 1922). "The ingestion of yeast in liberal portions is known to produce a laxative effect. In some cases, particularly in young children, such use of yeast has been followed by intestinal distention, doubtless attributed to fermentative gas production by the surviving yeast cells. There is, however, a preponderance of evidence regarding the advantageous use of yeast as a mild laxative. Aside from the objectionable possibility just referred to, there are no serious contraindications. Whether the laxative action of yeast is due to the survival of the living cells or to a chemical component of yeast which may also be present in dead cells is not clear at present. Yeast has often been recommended for internal administration because of its supposed beneficial effects on furuncles, acne, etc. Its adherents assert that it is almost a specific. Many, if not most, clinicians doubt this remarkable effect, which may, after all, be expected from any anticonstipation agent. Whether yeast or its products can provoke a leukocytosis likewise remains undemonstrated. Many of the conditions for which yeast and yeast preparations have been recommended therapeutically are so variable in their clinical course and so likely to show improvement without special treatment that the elaborate claims made in regard to yeast therapy for somewhat indefinite disorders must be largely discounted. It is not clear to what extent, if at all, live cultures of yeast may be used to change the intestinal flora, if, indeed, such a reaction becomes desirable in many of the conditions for which yeast is commonly used.

"Concentrated liquid extracts of yeast (which are rich in vitamin B) have long been used as substitutes for meat extracts in making bouillions and soup stocks, and it is asserted that meat extract is sometimes adulterated with yeast. Yeast vitamin concentrates have been prepared from extracts of yeast by a variety of methods."

WANTED — Male Nurse - Companion wants steady position. Age 26; sunny disposition. College education, French, German, Italian; traveled extensively. Large experience as nurse and also as social secretary. Expert in catheterization. Steady position wanted. Highest references from best doctors and families. Go anywhere. Address B. R., care of State Journal.

Did you ever try this test for purity of Nitrous Oxid?

Invert a full cylinder of Nitrous Oxid and blow contents on a piece of blotting paper—

By Inverting

the cylinder, the liquid portion of the gas will come in contact with the valve where the major portion of the usual impurities present in impure Nitrous Oxid will be concentrated —

The Result

should be a formation of crystal white Nitrous Oxid snow, which will quickly evaporate leaving absolutely no stain on your blotting paper.

We can furnish you with our RED STAR BRAND Nitrous Oxid and Medical Oxid in any quantity in the conventional sizes of government-inspected and approved cylinders. Our cylinders are equipped with the most modern, easily operating and positive acting valves of today.

FEE SCHEDULE
(Revised May 1, 1922)

BLOOD—	
Leucocyte Counts $3.00, Differential Leucocyte counts 3.00 — $5.00	$ 8.00
Red blood counts 3.00, Hemoglobin determinations 3.00 — $5.00	
Blood cultures	15.00
Blood smears for blood parasites, as malarial plasmodia	3.00
Blood group tests	5.00
Blood Chemistry (sugar, urea nitrogen, non-protein nitrogen, creatinin, uric acid, CO_2 combining power), single item	5.00
Each additional item	3.00
Wassermann tests—blood	5.00
Widal (agglutination) test	3.00
Coagulation and bleeding times	5.00
URINE—	
Urinalysis, routine	3.00
Phenolsulphonephthalein excretion	5.00
Microscopic examination for tubercle bacilli	3.00
Bacteriologic examination	5.00
STOOLS—	
Microscopic examination of stools	5.00
Examination of stools for invisible blood	3.00
Bacteriologic examination for typhoid and dysentery group	15.00
STOMACH CONTENTS—	
Chemic and microscopic examination of stomach contents	5.00
Test meal and obtaining contents for examination	5.00
SPUTUM—	
Microscopic examinations for tubercle bacilli	3.00
Pneumococcus typing with mouse method	15.00
Cultural examination	10.00
EXUDATES—	
Bacteriologic and microscopic examination of exudates	5.00
Diphtheria	5.00
Cerebro-spinal fluid examinations for syphilis (Wassermann test, cell count, globulin test)	8.00
Colloidal Gold test	5.00
Microscopic examination of smears, as for gonococci and Vincent's angina, sent to the laboratory	3.00
LUMBAR PUNCTURES (without examination of fluids)	10.00
VON PIRQUET TUBERCULIN TEST	5.00
DARK FIELD EXAMINATION for spirochaetes	10.00
TISSUES—	
Tissue examination	10.00
Pathologic consultation at operation (frozen sections when necessary)	25.00
VACCINES—BACTERIAL	10.00
WATER—	
Bacteriologic examination	15.00
MILK—	
Chemic examination	5.00
Bacterial count	5.00
ANIMAL INOCULATION for tubercle bacilli	15.00

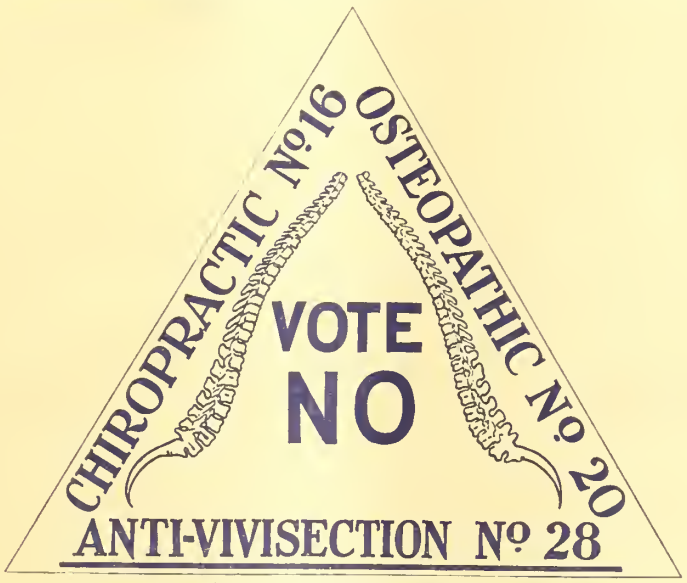
CALIFORNIA STATE JOURNAL OF MEDICINE



"THE OBTUSE TRIANGLE"

Chiropractic — Osteopathic — Anti-Vivisection Initiatives:

These three weird sisters meet again obtusely repeating the same old stories in the same old way. "Fair is foul and foul is fair" is still their campaign slogan. The three combined would permit the unqualified to practice unscientifically and prohibit the qualified from practicing scientifically.

DOCTOR'S OFFICE SET

Strong, sensible, full of cleanliness, a fitting companion in office hours, here is office equipment conveying a modern note to the Doctor's Office.

If clothes make the man, furniture makes the office.

Aseptic, spotless cleanliness is the prime requisite. Successful office practice is hindered without it. This beautiful white set fills the need.

There's an instrument cabinet, irrigator stand with two basins, revolving surgeons' stool, instrument and dressing stand, patients' chair, waste receptacle and a handsome examining, treatment and operating table. Seven pieces in all — the finest product of a modern factory.

After hours, when the dustman is about, a damp cloth, a rub or two, and zip!—it's just like a dish again. White as driven snow—the finish is put on to stay on.

To introduce the set, it is priced just right—from manufacturer to you—$154.75, plus the freight from Seattle. And, as for terms: if you like, there is an installment plan to suit.

Write a postcard for measurements and pictures. Your set is ready. Do not delay. Delivery in October only at this price.

91-99 DRUMM ST. Reid Bros INCORPORATED SAN FRANCISCO

Lederle Antitoxin Laboratories: Pearl River, Rockland County, New York

THE Lederle Antitoxin Laboratories were organized in 1906 for the purpose of introducing to the medical profession the Refined and Concentrated Diphtheria Antitoxin as perfected by the New York City Department of Health.

Since then the Lederle Antitoxin Laboratories have increased their field of endeavor and now prepare practically all the biological products of proven merit.

The Management of an Infant's Diet

In extreme emaciation, which is a characteristic symptom of conditions commonly known as

Malnutrition,
Marasmus or Atrophy

it is difficult to give fat in sufficient amounts to satisfy the nutritive needs; therefore, it is necessary to meet this emergency by substituting some other energy-giving food element. Carbohydrates in the form of maltose and dextrins in the proportion that is found in

Mellin's Food

are especially adapted to the requirements, for such carbohydrates are readily assimilated and at once furnish heat and energy so greatly needed by these poorly nourished infants.

The method of preparing the diet and suggestions for meeting individual conditions sent to physicians upon request.

Mellin's Food Company, **Boston, Mass.**

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) $45.00 per week and upward.

ANNOUNCES

THAT ITS X-RAY DEPARTMENT IS NOW EQUIPPED

WITH A

MODERN DEEP THERAPY X-RAY APPARATUS

FOR THE

PRE- AND POST-OPERATIVE RADIATION OF
DEEP MALIGNANCY

AND THE

TREATMENT OF INOPERABLE MALIGNANT CONDITIONS

This type of apparatus with its ability to produce a voltage of 280,000 volts (about twice the voltage capacity of X-ray machines hitherto available) gives an X-ray beam of enormously magnified penetrating power as compared to those previously in use.

Heavy filtration is used as an added factor in increasing the ratio of the depth to the skin dose, thus markedly decreasing the liability of injurious skin effects while as markedly increasing the effect on the deep tissues.

Very prosperous region; best highways in state. FIRST BEST (REASONABLE) OFFER GETS THIS. Address, Dr. J. K., care of Cal. State Journal.

Buying Power
of Our Members

There are 3842 members of the Medical Society of the State of California and readers of this Journal, located in every important city and town of this State.

This means 3842 circles of practice, which touch and influence over 1,921,000 people in the homes, industries and institutions throughout the State.

Think of the BUYING POWER of these physicians! If their average expenditure is only $1000, that amounts to $3,842,000 a year. But medical supplies bought on physicians' prescriptions, and goods purchased on their orders or recommendations for Sanitariums, Hospitals, Boards of Health, etc., would fully equal that amount—or a total of $7,500,000.

If members will give preference in all their buying to advertisers in their State Medical Journal, other advertisers will want space, and the publishers can then print a LARGER and BETTER Journal.

If you do not find advertised here the goods you want, please write the Journal. We will secure the information for you.

THE SANITARIUM WITH A PERSONALITY

Address all communications to Medical Director, Ross Sanitarium, Ross, California

What Is It Worth To Be *Sure?*

TO the physician treating a case of diphtheria or immunizing a child prophylactically, what is it worth to be sure that the Antitoxin or Toxin-Antitoxin used is absolutely dependable? What is it worth to know that he is fighting the disease with products both safe and potent?

The efficacy of Antitoxin and Toxin-Antitoxin in the control of diphtheria has been definitely established. The dependability of these products is predicated on that of the laboratory which makes them. Equipment, personnel, supervision—all of these must be of a high order to insure a trustworthy product. But above all the laboratory supplying these vitally important immunizing agents must be dominated by ideals of service and must be deeply conscious of its responsibility.

"DIPHTHERIA IMMUNIZATION," a reprint, sent on request. Write nearest branch: Detroit, New York, Chicago, Kansas City, Baltimore, New Orleans, St. Louis, Minneapolis, or Seattle.

Parke, Davis & Company

Gastric Disorders

Gastric disorder is essentially a problem of nutrition. How and with what to feed become questions of vital importance.

That "Ovaltine" will nourish when other forms of nourishment are badly borne or rejected by the patient is the burden of numerous medical reports received from physicians in all parts of the world.

"Ovaltine" too, is well adapted to duodenal or rectal feeding. In the latter, reports show that it is well absorbed and effective in maintaining the general health of the patient until oral feeding can be resumed.

"Ovaltine" has been extensively used in such conditions as Gastric Ulcer, Gastritis, Gastric Carcinoma, Stomach Atony, the Dyspepsias or wherever there is Nausea, Anorexia or other obstacle to normal alimentation.

OVALTINE

Supplied by druggists at 50c, 80c, $1.50 and $5.00

Samples and literature mailed to physicians upon signed request.

Quartz Light Therapy in Skin Diseases—Quartz light, E. Lawrence Oliver, Boston (Journal A. M. A., August 19, 1922), says, is of value especially in those ulcers dependent on poor peripheral circulation. Of these, the most frequent to be encountered are varicose ulcers of the leg, and in many of these quartz light may be a great help by producing an active hyperemia, which seems to be a great stimulus to epithelial proliferation. A few exposures of from one to three minutes (at weekly intervals) at a distance of ten inches from the source of light, an air-cooled lamp being used, are often sufficient to clean up a foul ulcer and start proliferation of epithelium at the borders. In traumatic ulcers also, healing may be greatly hastened. When skin grafts are indicated, and the local conditions are unfavorable, the use of quartz light for a few weeks previous to the operation will often greatly increase the likelihood of a successful result, by promoting the local circulation. Birthmarks of the so-called port wine type often respond extremely well to the water-cooled type of quartz lamp. In cases of alopecia areata, in which bald patches have existed for months or years, the hair has grown in again after five or six treatments with quartz light. In localized patches of chronic eczema, when there is a marked thickening of the skin, the results from quartz light therapy are often remarkable; permanent cures are not uncommon. Severe cases of acne vulgaris are sometimes benefited by the stimulation of quartz light treatments with the air-cooled lamp, but the good results are usually only temporary. In selected cases of lupus vulgaris, quartz light often proves of great value; in fact, in some cases it seems to be curative. In lupus erythematosus, ultraviolet light treatment is rarely the method of choice.

San Francisco Polyclinic and Post Graduate Medical College

FOUNDED 1889

Announcement of Graduate Courses

THE San Francisco Polyclinic and Post Graduate College has reorganized its teaching staff for the purpose of resuming the post graduate instruction that was interrupted by the world war. San Francisco, on account of its central location, its great hospitals and universities, offers unusual facilities for graduates in medicine to obtain opportunities for Post Graduate study.

Systematic courses in all branches of medicine and surgery are given. The next series begins September 1, 1922.

Attention is called to the two weeks' course in **operative technique.** Operations are performed by the student on the living dogs after preliminary demonstrations on the cadaver of the surgical anatomy of each operation.

Courses are also given in surgery of the Tonsils, Fractures, Orthopedics, Urology, Proctology, Opthalmology, Rhinology, Laryngology, Otology, Roentgenology, Obstetrics and Radio-therapy. All courses are practical in character and illustrated by clinical demonstrations, lantern slides, etc. A general course can also be arranged. For details, apply to

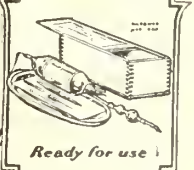
NEW YORK



Colfax School for the Tuberculous

Experience has shown that Sanatorium treatment is the most efficient and most approved method of treating the tuberculous. Those patients who are able to take advantage of the superior facilities offered by sanatorium treatment should not be denied the opportunity of receiving these benefits.

The cottage colony of the Colfax School for the Tuberculous provides accommodations for patients who have not only all the advantages of the sanatorium regime and supervision but at the same time have the benefit of home cooking and surroundings. While the patient improves the other members of the family daily receive instructions relative to those things everyone should know regarding tuberculosis.

Information regarding the methods of treatment and other details of interest to the physician and his patient are given in a booklet which will be sent on request.

The HOOD Improved Heatless HEAD LIGHT

Fits as comfortably as an old hat and delivers a maximum of clear, shadow-free light just where you want it. The head band is soft, pliable leather, well padded at the forehead and fitted with slide buckle, making it instantly adjustable. The air cooled Mazda bulb eliminates heating, and the light-weight, polished reflector throws the light without shadow. Each head lamp has 7 feet of silk cord, detachable from the head band and made with special connector for quick separation, allowing operator to leave the range of the cord. Light and cord quickly detachable so head band may be conveniently used with head mirror or binocular loupe.

The Chiropractor and the X-ray—It is interesting to note that the chiropractor has taken advantage of one of the greatest aids to medical practice, the X-ray, only to use it in a pseudo-scientific manner which does impress certain patients, but must react in the end to his own disadvantage. Chiropractors are now in the habit of sending their patients for X-ray examinations of the spine, but they will permit no interpretation of these plates except by themselves. Any little irregularity in alignment due to the position in which the patient is lying when the picture is made or due to a tilt in the tube, is pounced upon as an indication that the spine is out of plumb. This method of examination impresses the average intelligent person as being scientific, unless he thinks deeply in the matter or has his attention called to it by some physician familiar with the physics of the X-ray. This means that considerable harm is being done, and considerable money is necessarily taken from patients, many of whom can ill afford it.—Editorial, Rhode Island Medical Journal.

Alcoholic and Drug Addictions

EXCLUSIVE PUBLICATION—Articles are accepted for publication on condition that they are contributed solely to this journal. Rules governing publication and method of preparing illustrations furnished on request.

Advertising: Ethical and Otherwise—Under this title the Journal of the Oklahoma State Medical Association says in part:

"Another vexatious phase, one sure to cause trouble in the future, is the unwarranted and inexcusable custom lately adopted by certain 'small-town' hospital organizations by which they publish or influence publication of lists of patients recently 'operated upon at So and So Hospital.' In the first place, the practice borders on mountebank tactics; it appears instantly to the refined as impossible practice, it brands the perpetrator as of unenviable grade in the scale of professional attainment, and in certain cases it is nothing more or less than dishonest practice. The plea that it is not the individual physician connected with the hospital, but the hospital itself doing the advertising is unacceptable as explaining and condoning the practice from any viewpoint. The injustice of this class of impropriety lies in the fact that it advertises and gives supposed preferment to a few individuals only. By no means may other physicians, equally or better qualified professionally, participate in such advantage, if, indeed, it is an advantage. The practice at once places the beneficiaries in a position of advantage which cannot be acquired by others in the same vicinity. Any maneuver or activity giving preferment or monopolistic position to the few, and which cannot be enjoyed by all, is an impropriety to say the least. That it is rapidly coming to the time where a reckoning must be had goes without saying. It seems to be the safest plan or rule that any action or practice of the individual not generally practiced by his colleagues in that vicinity should be avoided and condemned."

Nevada State Medical Association—The nineteenth annual session of the Nevada State Medical Association will be held at Bower's Mansion, Nevada, on Friday, October 6, and Saturday, October 7, 1922. Ralph Alvin Bowdle, president; Horace J. Brown, secretary-treasurer.

MEAD'S

UNDERSTANDING

Consult the Doctor First

MEAD'S DEXTRI-MALTOSE FOR INFANT FEEDING

Every now and then a mother with an incomplete knowledge of infant feeding will proceed to feed her baby without the advice of her physician.

The infant will seem to do well for awhile. And then comes trouble, and more trouble. Another failure is chalked up to Misunderstanding.

Infant Feeding can either be a properly managed matter, with success in most cases, or a most miserable failure. Feedings that are adjusted by the physician to suit the individual baby, and directed with knowledge, experience and understanding, are almost certain to succeed. Feedings offered to the baby without the advice of the doctor, are almost certain to fail.

MEAD'S DEXTRI-MALTOSE, with cow's milk and water plus the doctor's written formula, offers the shortest road to UNDERSTANDING.

Please Write for Samples and Literature

THE MEAD JOHNSON POLICY

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant. Literature furnished only to physicians.

WANTED—Physician, well trained in surgery; graduate of Class A medical school, wants association with a surgeon who desires to retire later, or a general practitioner who wishes someone to do surgery. Will consider salary position for a time or partnership. Capable of hard work. Army experience. Best references. Address S. W. W., care of State Journal.

Psychoanalysis Analyzed—Maxwell Bodenheim believes that the time has come even when a note of warning must be sounded regarding the procedure and practice of psychoanalysis. In the New York Nation Bodenheim says: "Psychoanalysis is the spoiled child of a realistic age, and its boisterous manners should be corrected by a metaphysical spanking. . . . All that the psychoanalysts have done is shrewdly to reclassify, and in some instances clarify, the obstructing physical surface of man's conduct and emotions, and after probing this surface they have stopped, mistaking their inch for a complete world. They have resembled strangely scientific street urchins twiddling their thumbs and fingers as a mysticism that has existed since the beginning of man, and this gesture has had a pernicious influence over American literature during the past ten years."

ALKALINE THERAPY

CALSO WATER

A sparkling, palatable drinking water rich in ALKALI and a positive aid to your therapy.

CALSO WATER is made of distilled water and the salts normally present in the human body. It is rich in Calcium and Magnesium, and its use is indicated in all cases of body tissue acidocis. Its merit has been endorsed by many physicians.

Dr. King's Sanatorium

(THE BANNING SANATORIUM)

Banning (Riverside County) California

This well known institution (for the treatment of tuberculosis of the throat and chest) has recently been rebuilt and enlarged. The City of Banning (suffering from phthisiophobia) passed a "zoning" ordinance that forced abandonment of the former site of this sanatorium. A new site was purchased. An injunction was sought to prevent the use of the new site for sanatorium purposes. A temporary injunction was granted but, at the final hearing, this injunction was dissolved and the right to build and maintain the sanatorium was established. Many of the most prominent physicians in the state contributed testimony that enabled us to win the suit. During the progress of these suits the institution found it difficult to provide for patients demanding admission. Now, however, in its new quarters, it is prepared to accept all who apply. To physicians who are unfamiliar with our work we will gladly furnish references to other physicians (in almost every town in California) who have had patients or relatives in this institution. A circular describing conditions and containing rates will be mailed upon request. Address

DRS. KING and BRAMKAMP. BANNING, CALIFORNIA.

DIRECTLY and INDIRECTLY

Liquid Peptonoids

IS AN IMPORTANT NUTRITIONAL AID IN THE SICK ROOM

DIRECTLY

BECAUSE it is acceptable when all other food is rejected *and* offers immediately available nitrogen *and* calories — in sufficient amounts to be *of* real importance in emergency feeding—THEREBY saving tissue waste *and* preventing collapse.

INDIRECTLY

BECAUSE it sets the digestive pendulum in motion, kindles the appetite *and* creates food tolerance — THUS speeding the moment when more substantial nourishment may be added to the dietary.

Also DRY PEPTONOIDS (Soluble). 40% Protein—51.5% Carbohydrate.

Money Doubles

in twelve years if invested at 6% with interest compounded.

If your surplus money is not invested or is not earning a fair rate of interest, that money is not of full value to you.

One of the simplest and most profitable forms of investment is in well-secured bonds issued by Governments and Municipalities, or by prosperous and growing corporations.

This type of investment requires almost no personal attention. The income is available in convenient form and principal is readily accessible should occasion require.

The services of our organization are offered to you in the selection of bonds. We are not brokers, but merchants of securities, purchasing outright, only after careful investigation, the bonds we offer; consequently, we must be *absolutely sure* as to the value of the security.

We shall be glad to serve you by suggestions or recommendations. If agreeable, we would like to include your name among those to whom we make regular offerings of bonds. We invite your inquiry.

The Romance of Radium

1. THE DISCOVERY

The Romance of Radium had its beginning in 1896, when Marie Sklodowska Curie, then a post graduate student at the University of Paris, began an investigation and study of the newly discovered Becquerel rays, which uranium was found to emit,—rays with power to penetrate thick and light-proof paper and, after such penetration, to fog a photographic plate.

In 1898, after two years of ceaseless research, Madame Curie, assisted by her husband, separated two new radio-active elements in crude form from pitch blende. The more active of these she named radium. After further years of tedious work on a larger scale, she finally prepared a small amount of pure radium chloride. In 1903, with characteristic generosity, part of this precious material was given to Dr. Danlos, of the St. Louis Hospital in Paris, for medical research.

Such was the beginning, but where this fascinating romance will end no one knows.

Our Service

An immediately available supply of standard radium tubes, needles and plaques, under seal of the United States Bureau of Standards; quality guaranteed by the Standard Chemical Company, the pioneer American and world's largest producer of radium.

Necessary instruments and screens for the safe handling and application of radium.

A comprehensive and scientific course of instruction in the physics and therapeutic use of radium.

A loose-leaf Compendium of Abstracts of professional papers, showing the technic and results of radium treatment, with supplements as issued.

"RADIUM"—a quarterly journal, the oldest publication devoted exclusively to the therapeutics of radium.

Complete installations of the latest apparatus for the collection, purification, tubing and measurement of radium emanation.

Medical and technical experts always available for conference or for advice by letter.

Skilled assistance in seeking lost radium.

FOR SALE—$6,000 buys one of the finest locations in Northern California. Lot located on main street of town, consisting of 150 feet front by 100 feet deep, with fine residence and office. Finest agricultural section in State. 100% collections. Competent surgeon can work into a good paying practice right away. Two other physicians in town—competition just right. Modern 14-bed hospital, with up-to-date X-ray laboratory in town. Buyer must be able to handle $1,000 worth of stock in hospital. To the man who wishes to get away from the heat and locate in the cool, bracing climate of Northern California, this is an opportunity of a lifetime. Address F. M., care of State Journal.

WANTED—Position with group in a California city. Specialty: Eye, Ear, Nose and Throat. Have had two years' training in Europe, just returning. Graduate of a California medical college; have California license. Address Dr. O. E. G., Box 176, Ames, Iowa.

The Real Things in Medicine—The minimum requirements for a career in medicine are a preliminary education, four years in a medical school, and a license to practice. While these requirements are indispensable, they are by no means sufficient. Three higher attributes stand out as real elements that make for a successful physician; without these, real success in medicine is impossible—brains, culture, and character. . . .

No encouragement should be extended to those about to enter the profession of medicine or to those already in to continue, unless they are supplied abundantly with gray matter. The misfits in medicine, as well as in other occupations, are due largely to a lack of understanding. There are some in the corn-field who ought to be in medicine; there are some in medicine who ought to be in the corn-field. . . .

A finely endowed intellect is needed to carry on in the realm of science, to withstand its temptations toward the illogical, to keep clear-headed in the midst of fact and fancy. Such endowment comes not from science itself; it issues permanently from a mind nurtured in the ways of thinking. The handmaiden of brains, essential for the physician, is common sense, which is simply the ability to put brains to good account. In the words of Holmes, "Science is a first-rate piece of furniture for a man's upper chamber if he has common sense on the ground floor. But if a man hasn't got plenty of good common sense, the more science he has the worse for his patient."

Make no mistake about culture. Culture is refinement, accuracy, poise, resourcefulness; it is not effeminacy, weakness, conventionalism, impracticability.

Detracting not one whit from the appeal for better mental equipment, it appears even more timely to emphasize the greater need for moral qualification in the physician. By this no reference is meant to righteousness or to worlds to come, to religion or to denominationalism, but only to the possession of a sound moral sense. The character of a physician is his most priceless property. It is what he stands for and whom he stands for; it is his attitude toward life; it is "what God sees him do in the dark." Truth is the goal; it develops character, and character tells in one's work. Too many are entering the medical profession without good working consciences, without a keen appreciation of the difference between right and wrong; too many are coming into an honored and honorable calling with low standards of trade and traffic in their souls; too many get in who are not gentlemen to begin with, and cannot be made gentlemen to end with. Today the young physician too frequently feels compelled to ask his associates, "What do I get out of it?" when he might better ask himself, "What am I putting into it?"

Medicine is both a science and an art; it has to do both with knowing and with doing. It is not an exact science—more's the credit, for exact sciences are inert and uninteresting. But the one big asset for the medical man is the acquisition of the scientific attitude in his student days. Every physician should remain a student the whole of his natural life. A pitiable sight is the practitioner who was known as a "good student," but who, after five years more or less, has degenerated into a routinist, never reviewing his former knowledge or adding to his original store. Such a man, though perhaps skilled in so-called practical affairs, forgets more and more medicine each year, until finally it is difficult for him to keep up. He begins to decry theory and to extol practice; he thinks only of results and never of causes; he speaks magnificently of "common sense" and "letting Nature take its course," but rarely uses the one or permits the other.—Hubert A. Royster, M. D., in Jour. A. M. A., August 5, 1922.

THE KROMAYER LAMP

Consider—

that the Kromayer lamp enjoys the distinction for highest intensity of Ultra-Violet radiation and the most practical means for administering treatment of many conditions.

The effective results obtained with its use over a period of ten years has been the stimulant for our scientific research work that has resulted in bringing the lamp to its present high state of efficiency.

It is chosen as the most desirable method of applying actinic rays to Lupus, Naevus, Acne, Psoriasis, Eczema, Ulcers and Wounds; to specific or non-specific orificial inflammatory conditions such as Tubercular Laryngitis, Rectal Fistulae, Otitis Media, Frontal Sinus Infections, Ozena and a number of gynecological conditions.

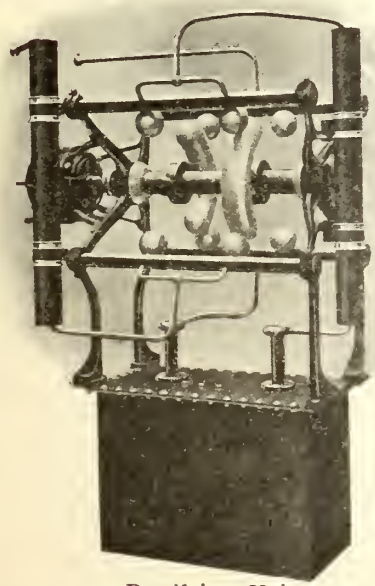
INTERNATIONAL

INTERRUPTERLESS X-RAY MACHINE



Rectifying Unit

Precision Type

The INTERNATIONAL X-Ray Apparatus of the Interrupterless type is offered as the greatest improvement in X-Ray apparatus for over ten years. Constant form of rectification is obtained by having designed a rectifier which has the characteristics of a sphere gap and not that of a pointed gap. The sphere gap characteristics eliminate inconsistencies of the point gaps and substantially do away with corona discharge and obnoxious gases; while with all meters at ground potentiality, the danger of accidental contact which exists in the usual high tension equipment is eliminated. Transformers are designed along the general lines, but with added insulation to keep them in advance of anything else offered on the market.

ANNOUNCEMENT

Members of the Medical Society of California, Advertisers in the State Journal, or any individual or firm authorized by the Medical Society may now have access to the only

Official Mailing List

of the

MEDICAL SOCIETY OF THE STATE OF CALIFORNIA

This list comprises *all* the members of the Medical Society, arranged by counties, and is carefully kept up to date, being revised every thirty days.

By authority of the State Council, we are permitted to offer you the use of this list for any legitimate addressing purpose. APPROVAL OF THE SECRETARY OF THE STATE SOCIETY IS ESSENTIAL IN ALL CASES.

The rates are reasonable and you are assured of having your addressed matter *reach* the parties addressed.

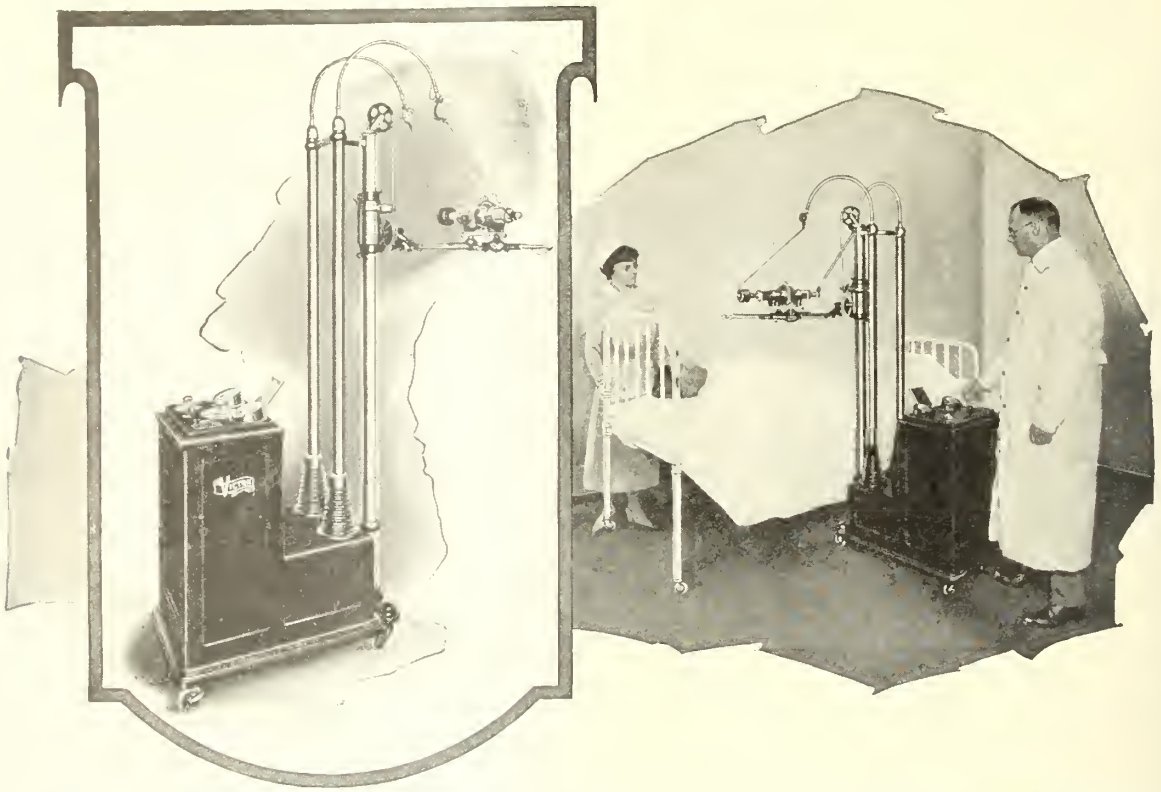
WRITE OR PHONE

THE JAMES H. BARRY COMPANY

1122-1124 Mission Street, San Francisco

Phone Park 6380

Note:—All addressing is handled under the personal supervision of Mr. Wm. H. Barry, Superintendent of Publications, Medical Society of the State of California.



This New Victor X-Ray Outfit Is Radically Different

It Is a *Stabilized* Mobile Unit

What the Stabilizer Does

When the voltage of the line supply current fluctuates (this condition prevails on practically every line) the Victor-Kearsley Stabilizer, incorporated in this unit, acts *automatically* to hold the milliamperage constant in the Coolidge Tube—the exact milliamperage desired for the radiograph. 100% radiographic results are therefore insured—no "retakes" necessary because of fluctuating line supply.

Control Features

Auto-transformer allows selection of any penetration desired from 2 to 5 inches, divided into 26 steps—a fineness of graduation that is distinctive in this outfit. The stabilizer permits selection of any milliamperage from 2 to 30, at any setting of the auto-transformer. A chart on the control board helps the operator to obtain instantly any current value.

Circuit Breaker Safety Device

In case of "overload" beyond the capacity of the tube (30 Ma. at 5" back-up spark) this device *automatically* shuts off current supply, preventing damage to tube and apparatus. Consider also the importance of this from the standpoint of protection to both operator and patient, in case of accidental contact with the high tension system.

A Complete X-Ray Unit

Where only limited space is available in the physician's office, the compactness of the Victor Stabilized Mobile X-Ray Unit solves the problem. Mounted on casters and easily moved about, it lends itself to varied demands. It also becomes an extremely valuable addition to any existing hospital equipment.

The Victor-Kearsley Stabilizer is one of the most important X-Ray developments since the advent of the Coolidge Tube itself. It should not be confused with other devices which tend to stabilize only the current to the filament of the tube. The important advantages of this unit are fully explained in a special bulletin, which we will gladly send you on request.

CINCHOPHEN
ABBOTT

The genuine Council-passed drug, called by its correct and ethical American name. For the home profession. The equal of the best ever imported. Specify it when prescribing. Insist on it when ordering.

Effective in most instances for the relief of pain in **acute rheumatism, gout, arthritis, neuritis, lumbago, sciatica, migraines**, etc. Considered safer than the salicylates. A prudent change from coaltar anodynes.

Prices Reduced.—This excellent drug deserves the widest usage. We are glad, therefore, to announce the following substantial reduction from the old prices: **For the tablets, 100, $2.25 net; for the powder, 4 ounces, $5.15 net.**

Your druggist has **Cinchophen, Abbott**, or will procure it for your prescriptions. If not, order from us direct.

RED STAR BRAND NITROUS OXIDE AND MEDICAL OXYGEN

CARNEGIE INSTITUTE OF TECHNOLOGY

SCHENLEY PARK PITTSBURGH

Department of Chemistry,
26 August 1922.

REPORT ON THE ANALYSIS OF NITROUS OXIDE

Sample submitted by the Western Nitrous Oxide Company, San Francisco, California.

Carbon Dioxide	0.00 per cent
Oxygen	0.12 " "
Nitrous Oxide	98.89 " "
Moisture	0.67 " "
Nitrogen(by diff.)	0.32 " "
HCl	Nil
Chlorine	Nil
Oxides on Nitrogen NO and NO_2	Nil

L. H. Miller

L.H.Miller,
Instructor of Chemistry

NOTE—Analysis shows 98.89 per cent pure Nitrous Oxide, diluted 1.11 per cent, consisting of Oxygen, Moisture and Nitrogen, a dilution containing absolutely no harmful ingredient.

This sample was taken from a 420 gallon standard cylinder, which when empty holds at atmospheric pressure 1¼ gallons of atmospheric air, which is .31 per cent of the total 420 gallons in the sample submitted, making the manufacturing purity 99.20 per cent Nitrous Oxide.

WESTERN NITROUS OXIDE COMPANY

LABORATORY: TENTH & FOLSOM STS.
SAN FRANCISCO, CALIFORNIA

We carry in stock a full line of standard Anti-toxins, Serums, Vaccines, Hypodermic Syringes and Needles. Neo-salvarsan and other preparations used hypodermatically and intravenously.

FEE SCHEDULE
(Revised May 1, 1922)

BLOOD—	
Leucocyte Counts $3.00 } Differential Leucocyte counts 3.00 } $5.00	$ 8.00
Red blood counts 3.00 } Hemoglobin determinations 3.00 } $5.00	
Blood cultures	15.00
Blood smears for blood parasites, as malarial plasmodia	3.00
Blood group tests	5.00
Blood Chemistry (sugar, urea nitrogen, non-protein nitrogen, creatinin, uric acid, CO_2 combining power), single item	5.00
Each additional item	3.00
Wassermann tests—blood	5.00
Widal (agglutination) test	3.00
Coagulation and bleeding times	5.00
URINE—	
Urinalysis, routine	3.00
Phenolsulphonephthalein excretion	5.00
Microscopic examination for tubercle bacilli	3.00
Bacteriologic examination	5.00
STOOLS—	
Microscopic examination of stools	5.00
Examination of stools for invisible blood	3.00
Bacteriologic examination for typhoid and dysentery group	15.00
STOMACH CONTENTS—	
Chemic and microscopic examination of stomach contents	5.00
Test meal and obtaining contents for examination	5.00
SPUTUM—	
Microscopic examinations for tubercle bacilli	3.00
Pneumococcus typing with mouse method	15.00
Cultural examination	10.00
EXUDATES—	
Bacteriologic and microscopic examination of exudates	5.00
Diphtheria	5.00
Cerebro-spinal fluid examinations for syphilis (Wassermann test, cell count, globulin test)	8.00
Colloidal Gold test	5.00
Microscopic examination of smears, as for gonococci and Vincent's angina, sent to the laboratory	3.00
LUMBAR PUNCTURES (without examination of fluids)	10.00
VON PIRQUET TUBERCULIN TEST	5.00
DARK FIELD EXAMINATION for spirochaetes	10.00
TISSUES—	
Tissue examination	10.00
Pathologic consultation at operation (frozen sections when necessary)	25.00
VACCINES—BACTERIAL	10.00
WATER—	
Bacteriologic examination	15.00
MILK—	
Chemic examination	5.00
Bacterial count	5.00
ANIMAL INOCULATION for tubercle bacilli	15.00
BASAL METABOLISM DETERMINATION	15.00
BLOOD TRANSFUSION (not including cost of donors)	$100.00 to 150.00
EXAMINATION OF ANIMAL BRAINS FOR RABIES	15.00
ANTI-RABIC TREATMENT, 21 injections, including vaccine material	150.00
POST-MORTEM examinations by special arrangement.

CALIFORNIA STATE JOURNAL OF MEDICINE

PHYSICIANS' OFFICES AS "HEALTH CENTERS"

WHEREAS, It always has been and is the primary purpose of physicians to give trained, scientific, sympathetic service to all of their fellow citizens who need medical advice and to furnish this service to all alike, regardless of the social or financial standing of the patient, and

Whereas, It never has been and is not now necessary to interpose any agency not under the direct supervision and control of competent members of the medical profession, members are reminded of the dangers of co-operation in agencies where such supervision and control does not exist, and

Whereas, In order to re-emphasize these policies and practices to all citizens of California, and to counteract the influences going about the state to the effect that consideration by physicians for those needing medical advice can be obtained only by applying to some non-medical organization, and in order that the public may be fully informed and free to call directly upon the physician of its choice with the assurance of sympathetic and confidential consideration, therefore, be it

Resolved, By the Medical Society of the State of California and representatives of all county and other constituent organizations, in convention assembled, that the office of each of its 4000 members throughout the state is a "Health Center" of the kind that means the best medicine and public health advice that physicians can give; this upon the basis that those who can pay in full should do so, those who can pay part should do so, and those who are unable to pay should have the service without cost.

Resolved, That in order to secure special financial consideration, the patient is requested to execute and sign a paper showing his socio-financial status and setting forth briefly the reasons why he must ask for special financial consideration, this being the policy now being followed by clinics and welfare organizations of all sorts.—(*Resolution passed by the House of Delegates of the Medical Society of the State of California at the Fifty-First Annual Session, May 17, 1922.*)

PORCELLO

DOCTOR'S OFFICE SET

Strong, sensible, full of cleanliness, a fitting companion in office hours, here is office equipment conveying a modern note to the Doctor's Office.

If clothes make the man, furniture makes the office.

Aseptic, spotless cleanliness is the prime requisite. Successful office practice is hindered without it. This beautiful white set fills the need.

There's an instrument cabinet, irrigator stand with two basins, revolving surgeons' stool, instrument and dressing stand, patients' chair, waste receptacle and a handsome examining, treatment and operating table. Seven pieces in all — the finest product of a modern factory.

After hours, when the dustman is about, a damp cloth, a rub or two, and zip!—it's just like a dish again. White as driven snow—the finish is put on to stay on.

To introduce the set, it is priced just right—from manufacturer to you—$154.75, plus the freight from Seattle. And, as for terms: if you like, there is an installment plan to suit.

Write a postcard for measurements and pictures. Your set is ready. Do not delay. Delivery in October only at this price.

91-99 DRUMM ST. Reid Bros INCORPORATED SAN FRANCISCO

Lederle Antitoxin Laboratories: Pearl River, Rockland County, New York

THE Lederle Antitoxin Laboratories were organized in 1906 for the purpose of introducing to the medical profession the Refined and Concentrated Diphtheria Antitoxin as perfected by the New York City Department of Health.

Since then the Lederle Antitoxin Laboratories have increased their field of endeavor and now prepare practically all the biological products of proven merit.

PASADENA, CALIFORNIA

AIRPLANE VIEW OF GROUNDS

A SANITARIUM FOR THE TREATMENT OF ALL FORMS OF NERVOUS DISORDERS AND GENERAL DISEASES

SIXTEEN MILES FROM LOS ANGELES, HEART OF THE ORANGE BELT

MAIN BUILDING

LOCATION—Situated in the foothills of the Sierra Madre Mountains, just outside of the city of Pasadena, is this beautiful sanitarium. It is surrounded by a natural live-oak grove of 20 acres, with lawns and gardens, ideally adapted to rest and enjoyment. Large central building and cottages all modernly equipped. Homelike and comfortable.

Climate Ideal.
Cuisine Excellent.
Outdoor Sports and Recreation.

EQUIPMENT—Special equipment for aiding in a correct diagnosis. The Laboratory, Hydrotherapy and Electricity Departments are important adjuncts to the general Sanitarium treatment. All forms of baths are given, including the famous Nauheim.

Dairy and Poultry Plant.
Rooms With or Without Baths.
Private Bungalows With Sleeping Porches.

CLASS OF PATIENTS — All forms of nervous disorders and general diseases are treated. Special attention is paid to Gastro-Intestinal disorders and Circulatory System. No Tuberculosis, Epilepsy or Insanity received.

BOARD OF DIRECTORS.— Norman Bridge, M. D., H. C. Brainerd, M. D., W. Jarvis Barlow, M. D., F. C. E. Mattison, M. D., Stephen Smith, M. D.

The Management of an Infant's Diet

Malnutrition, Marasmus or Atrophy

Mellin's Food
4 level tablespoonfuls
Skimmed Milk
8 fluidounces . .
Water
8 fluidounces . .

Analysis:

Fat . . .	.49
Protein . . .	2.28
Carbohydrates . .	6.59
Salts . . .	.58
Water . . .	90.06
	100.00

The principal carbohydrate in Mellin's Food is maltose, which seems to be particularly well adapted in the feeding of poorly nourished infants. Marked benefit may be expected by beginning with the above formula and gradually increasing the Mellin's Food until a gain in weight is observed. Relatively large amounts of Mellin's Food may be given, as maltose is immediately available nutrition. The limit of assimilation for maltose is much higher than other sugars, and the reason for increasing this energy-giving carbohydrate is the minimum amount of fat in the diet made necessary from the well-known inability of marasmic infants to digest enough fat to satisfy their nutritive needs.

Mellin's Food Company, Boston, Mass.

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) $45.00 per week and upward.

ANNOUNCES

THAT ITS X-RAY DEPARTMENT IS NOW EQUIPPED

WITH A

MODERN DEEP THERAPY X-RAY APPARATUS

FOR THE

PRE- AND POST-OPERATIVE RADIATION OF DEEP MALIGNANCY

AND THE

TREATMENT OF INOPERABLE MALIGNANT CONDITIONS

This type of apparatus with its ability to produce a voltage of 280,000 volts (about twice the voltage capacity of X-ray machines hitherto available) gives an X-ray beam of enormously magnified penetrating power as compared to those previously in use.

Heavy filtration is used as an added factor in increasing the ratio of the depth to the skin dose, thus markedly decreasing the liability of injurious skin effects while as markedly increasing the effect on the deep tissues.

Very prosperous region; best highways in state. FIRST BEST (REASONABLE) OFFER GETS THIS. Address, Dr. J. K., care of Cal. State Journal.

Buying Power
of Our Members

There are 3842 members of the Medical Society of the State of California and readers of this Journal, located in every important city and town of this State.

This means 3842 circles of practice, which touch and influence over 1,921,000 people in the homes, industries and institutions throughout the State.

Think of the BUYING POWER of these physicians! If their average expenditure is only $1000, that amounts to $3,842,000 a year. But medical supplies bought on physicians' prescriptions, and goods purchased on their orders or recommendations for Sanitariums, Hospitals, Boards of Health, etc., would fully equal that amount—or a total of $7,500,000.

If members will give preference in all their buying to advertisers in their State Medical Journal, other advertisers will want space, and the publishers can then print a LARGER and BETTER Journal.

If you do not find advertised here the goods you want, please write the Journal. We will secure the information for you.

Save the Tenth Child

STATISTICAL data show that approximately 10% of all children having Diphtheria die. Early and adequate Antitoxin treatment would save these children. In meeting this grave responsibility are you sure that your little patients are receiving the best Antitoxin obtainable? Do you have a satisfying consciousness of having done for them all that can be done?

The use of Parke, Davis & Company's Antitoxin inspires just that sort of confidence. For a quarter of a century it has been recognized as the standard the world over. It is potent, pure, and concentrated.

Parke, Davis & Company's Antitoxin is produced in a laboratory possessing unsurpassed facilities. Excellence in achievement here dominates all other interests.

"DIPHTHERIA IMMUNIZATION," a reprint, sent on request. Write nearest branch: Detroit, New York, Chicago, Kansas City, Baltimore, New Orleans, St. Louis, Minneapolis, or Seattle.

Parke, Davis & Company

Gastric Disorders

Gastric disorder is essentially a problem of nutrition. How and with what to feed become questions of vital importance.

That "Ovaltine" will nourish when other forms of nourishment are badly borne or rejected by the patient is the burden of numerous medical reports received from physicians in all parts of the world.

"Ovaltine" too, is well adapted to duodenal or rectal feeding. In the latter, reports show that it is well absorbed and effective in maintaining the general health of the patient until oral feeding can be resumed.

"Ovaltine" has been extensively used in such conditions as Gastric Ulcer, Gastritis, Gastric Carcinoma, Stomach Atony, the Dyspepsias or wherever there is Nausea, Anorexia or other obstacle to normal alimentation.

OVALTINE

Supplied by druggists at 50c, 80c, $1.50 and $5.00

Samples and literature mailed to physicians upon signed request.

604 Mission St.
SAN FRANCISCO CALIFORNIA

Tel. Sutter 1026

Professor Ernst Fuchs—During the early part of July Prof. Ernst Fuchs was the guest of the California Academy of Medicine in San Francisco. At the July dinner and meeting of the Academy he read an interesting paper on "The Endocrines and the Eye."

During the following three weeks he gave a course of lectures on the pathology of diseases of the eye. The course was attended by about thirty ophthalmologists from the western States. The lectures were illustrated with microscopical lantern slides.

While here Professor Fuchs was the guest at several dinners given in his honor by members of the profession. Every one who came in contact with him felt that Professor Fuchs truly merits the appelation of "The Father of Ophthalmology." His deep knowledge of his subject, his ability as a teacher and lecturer, together with his kindly interest in those with whom he comes in contact, have made him a host of friends through the west.

The superintendent who can get his board of trustees to dispense with the discussion of petty complaints and carping criticism around which their meetings are prone to center, who can lead them away for a short time from the business administration to the other angle of hospital administration, which bears on the medical service given, will find himself known as one of the real hospital administrators. Furthermore, he will secure for the people of the community in which his hospital is located a medical service such as has never before been thought possible. The day of the old type of superintendent is passing, and in his place is coming one who may rightly be called an expert.—S. G. Davidson, in The Modern Hospital, August, 1922.

ABDOMINAL SUPPORTS TRUSSES ELASTIC HOSIERY

Post-operative, maternity and hernia cases are especially well cared for in a unique and efficient manner. For twenty-one years we have made our business a study, and by confining ourselves to these specialties have developed methods that assure relief to the patient and satisfaction to the doctor.

Every physician should secure a copy of our catalogue, which explains our business in detail. We have the largest and best equipped plant on the Pacific Coast and are the exclusive agents for the famous Drs. Smith's "Honest John" Truss, the only practical device for holding at the internal ring.

TWO ESTABLISHMENTS

Clark-Gandion Truss Co.

Phone Market 7004 — 1108 Market St. San Francisco

Phone Oakland 8652 — 1522 Broadway Oakland

Not only does this Catalogue contain a complete line of standard instruments, dressings, rubber goods, bags, glassware, steel furniture, etc., but it includes as well, many new specialties that will be particularly interesting to you. The general mailing has been completed and if you have not received your copy just fill out the coupon and it will be sent to you at once. This catalogue may be accepted as establishing a standard of fair price and honest value.

ANNOUNCING

The Wappler Electric Company's latest model, "The Duplex X-Ray Machine." A double transformer machine for general radiographic and diagnostic work, and also designed to meet the demands of Deep Therapy up to a penetrative power of 200 K. V. at 6 M. A. Complete with Coolidge transformer control and meters at a price of $2200.

Write or call and discuss this outfit with us; it's real Wappler quality throughout, free from troublesome surges, gives long tube life, and has the kick.

Also ask for Bulletin No. 98 on the Wappler **Composite X-Ray Unit**—a universal table with tube stand attached, power plant and control in one assembly.

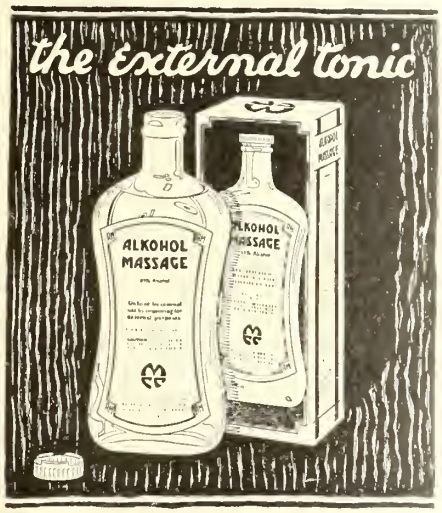
95% Ethyl Alcohol



An Important Development
In the Medication of Alcohol

After lengthy research the Mifflin Chemists have evolved a private formula which removes every drawback from the prescription of medicated alcohol.

Soothing and Odorless

Alkohol Massage, the result of the new formula, is really better than the old alcohol for external purposes. No wood alcohol, acetone, or other poisonous ingredients. Pleasant odor. Soothing, not injurious to the skin.

MIFFLIN
ALKOHOL
MASSAGE
the external tonic

Physicians' samples gladly sent on request will show how satisfactory it is.

Mifflin Chemical Corporation
Delaware Ave. and Tasker St.
PHILADELPHIA, U. S. A.

San Francisco Polyclinic and Post Graduate Medical College

FOUNDED 1889

Announcement of Graduate Courses

THE San Francisco Polyclinic and Post Graduate College has reorganized its teaching staff for the purpose of resuming the post graduate instruction that was interrupted by the world war. San Francisco, on account of its central location, its great hospitals and universities, offers unusual facilities for graduates in medicine to obtain opportunities for Post Graduate study.

Systematic courses in all branches of medicine and surgery are given. The next series begins September 1, 1922.

Attention is called to the two weeks' course in **operative technique.** Operations are performed by the student on the living dogs after preliminary demonstrations on the cadaver of the surgical anatomy of each operation.

Courses are also given in surgery of the Tonsils, Fractures, Orthopedics, Urology, Proctology, Opthalmology, Rhinology, Laryngology, Otology, Roentgenology, Obstetrics and Radio-therapy. All courses are practical in character and illustrated by clinical demonstrations, lantern slides, etc. A general course can also be arranged. For details, apply to

H. A. L. RYFKOGEL, M. D., Dean.

"To enable, by a simple vaccination, to pick out those who are naturally immune to diphtheria from those who are susceptible, is surely a diagnostic achievement. It is just so much greater because the test is harmless and prevents the unnecessary waste of expensive antitoxin, and it saves large numbers of children the inconvenience and annoyance of the injection itself.

"Far better to vaccinate against a possible infection than take a chance; and, better still, to know with a reasonable degree of assurance that such a vaccination is not necessary. Not to take precautions is to stand on a footing with the anti-vaccinationists."—Louisiana State Health Board Bulletin.

Eradicate diphtheria by Immunization

SCHICK TEST SQUIBB is a reliable diagnostic test for susceptibility to diphtheria. A safe guide in determining the need of Toxin-Antitoxin immunization.

DIPHTHERIA TOXIN-ANTITOXIN MIXTURE SQUIBB establishes an active immunity against diphtheria, lasting three years or longer. As easy to administer as typhoid vaccine.

DIPHTHERIA ANTITOXIN SQUIBB is isotonic with the blood. Small bulk, with a minimum of solids, insures rapid absorption and lessens the dangers of severe anaphylactic reaction.

MANUFACTURING CHEMISTS TO THE MEDICAL PROFESSION SINCE 1858

Colfax School for the Tuberculous

Experience has shown that Sanatorium treatment is the most efficient and most approved method of treating the tuberculous. Those patients who are able to take advantage of the superior facilities offered by sanatorium treatment should not be denied the opportunity of receiving these benefits.

The cottage colony of the Colfax School for the Tuberculous provides accommodations for patients who have not only all the advantages of the sanatorium regime and supervision but at the same time have the benefit of home cooking and surroundings. While the patient improves the other members of the family daily receive instructions relative to those things everyone should know regarding tuberculosis.

Information regarding the methods of treatment and other details of interest to the physician and his patient are given in a booklet which will be sent on request.

Studies on the Therapeutic Effect of Bacillus Acidophilus Milk and Lactose—Relief from chronic constipation and diarrhea has been secured by Nicholas Kopeloff and Clarence O. Cheney, New York (August 19, 1922), by the ingestion of B. acidophilus milk and lactose in mentally normal and psychotic subjects. This corroborates the work of Rettger and Cheplin. Five psychotic patients receiving such treatment showed no improvement in their mental conditions during the period of treatment; in two others, improvement was slight, but was not more than might have been expected without treatment with B. acidophilus milk, each of these patients having recovered previously from similar attacks without this treatment. The intestinal flora becomes changed on treatment with B. acidophilus whole milk and lactose, but the relative percentage of gram-positive rods rarely exceeds 70. Incubating B. acidophilus whole milk at room temperature is satisfactory for three or four days, after which the number of viable organisms decreases rather rapidly, and the acidity increases to the point of unpalatability.

Contributions to the Pharmacology and Therapeutics of Iodids—The investigations made by Earl D. Osborne, Rochester, Minn. (Journal A. M. A., August 19, 1922), suggest that the iodin given in the form of potassium iodid by mouth forms a sodium protein combination, while in the case of sodium iodid by mouth only traces of iodin enter into combination with the proteins. In a study not yet completed of two patients exhibiting symptoms of iodism following the administration of sodium iodid by mouth, the iodin united with the protein fraction to a greater extent than in normal persons. These observations have a direct bearing on the relative effectiveness of potassium and sodium iodid by mouth and the latter intravenously.

WANTED—Assistantship to San Francisco Surgeon. Age 31, married. Graduate 1916. Internships St. Vincent's, Bellevue, St. Mary's, St. Laurence Hospitals, New York. General practice four years. Address Dr. X, care of State Journal.

Vita Zest not Admitted to N. N. R.—The Council on Pharmacy and Chemistry reports that Vita Zest (Vita Zest Co., Inc., New York City) comes in the form of capsules, and is stated to be composed of 83⅓ per cent of "highly concentrated vitamin extracts" (Fat Soluble A, Water Soluble B, and Water Soluble C). The amount of material in each capsule is not declared nor is any information offered to show that the amount (or potency) of the three vitamins said to be contained in the vitamin extract is determined or controlled. Even if it were shown that the product contains appreciable amounts of vitamins, the claims advanced for it are such that most enthusiastic advocates of the administration of vitamin would scoff at them. The Council declared Vita Zest inadmissible to New and Non-official Remedies, because (1) its composition is indefinite; (2) it is exploited under unwarranted therapeutic claims and in a manner which tends to its indiscriminate use, and (3) because the name suggests its haphazard use as a general tonic.—Journal A. M. A., June 17, 1922, p. 1912.

ADVERTISEMENTS

The Journal is published on the fifth of the month. advertising copy must be received not later than the 15th of the month preceding issue. Advertising rates will be sent on request.

CONTRIBUTIONS

EXCLUSIVE PUBLICATION—Articles are accepted for publication on condition that they are contributed solely to this journal. Rules governing publication and method of preparing illustrations furnished on request.

A Study of Hypotension—A consideration of the blood pressure records in 440 cases of absolute hypotension and in 145 cases of relative hypotension suggests to Stewart R. Roberts, Atlanta, Ga. (Journal A. M. A., July 22, 1922), that hypotension seems to be equally well distributed between the sexes. Hypotension patients have proportionately more normal hearts than have normal persons or hypertension patients. As the pressure rises the heart is more likely to be diseased. The pulse rate is not a determining factor in hypotension. It tends to rise only very slightly with rising pressure. The rate of the pulse is more dependent on the sex than on the blood pressure. Hypotension may accompany different diseases. It is difficult to prove the influence of the disease in the causation of the hypotension because, as a rule, the pressure before disease is unknown. The lowest pressures occur in secondary anemia, pallagra, somasthenia, neuroses, tuberculosis and the acute infections of the respiratory tract. Relative hypotension is a term that should probably be restricted to persons of forty-five years and older whose pressure ranges between 111 and 119, both inclusive. The classification of hypotension is important because it separates hypotension in health from hypotension in disease and makes clearer the intricate problems of low blood pressure. Hypotension is not a bar to insurance in the old line companies, although in one series of 3389 accepted candidates, the death rate was two-thirds greater than the expectancy tables would indicate. Women seem to develop hypotension at an earlier age than men, as indicated by two series of cases. The percentage of the hemoglobin is not a determining factor in hypotension. In disease of the circulation, secondary anemia is the most common accompaniment of hypotension. Arteriosclerosis and myocardial diseases are relatively rare. Focal infections are common accompaniments of hypotension. In sick adult negroes there are more cases of absolute hypotension than of hyptertension. Hypotension seems to tend to accompany acute diseases characterized by fever and chronic diseases characterized by diarrheas, as amebic dysentery, sprue and pellagra.

THOSE physicians who have been called in the night to administer diphtheria antitoxin to a child appreciate the importance of a simple, workable syringe package.

The Lilly Syringe is an index to the merit of its contents. Its preparation for injection involves no loss of time or unnecessary effort. With it you can meet emergencies with confidence and assurance.

The only satisfactory way to become acquainted with this superior syringe is to use it. Ask your druggist to supply Lilly's Diphtheria Antitoxin. Write us for further information.

MEAD'S

Infant Diet Materials

Like many good things there is no mystery about Mead's Ethical Policy—but there is MUCH OF GOOD SENSE

Mead's Slogan—"Consult the Doctor First"

"MEAD'S DEXTRI-MALTOSE is an ethical infant diet material offered to physicians who wish to modify cow's milk for the individual requirements of babies."

MEAD'S "D-M" is not advertised in women's magazines, newspapers or any lay publications.

MEAD does not print feeding directions on the "D-M" package.

Satisfactory results—because the doctor's creative talent has full scope and he is not hindered by "outside interference."

A quality product marketed in this ethical manner must necessarily give results in most cases, since it is offered only for the consideration and approval of physicians.

THE DOCTOR'S CONFIDENCE IS NOT MISPLACED

THE MEAD JOHNSON POLICY

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant. Literature furnished only to physicians.

28,000 doctors asked us for literature this year
Will you please write for some, too?

BACILLUS

ACIDOPHILUS

Remarkable results are reported in the journals from the use of this bacillus in cases of intestinal disorder. Practically all of the investigators agree that this organism should be taken in milk.

We offer a bacillus acidophilus of unusual vigor, grown in milk. Many physicians are attaining success in the treatment of intestinal toxemias by the use of our strains of this bacillus, either in a pure culture or in symbiosis with the bacillus Bulgaricus.

Our cultures are distributed by the well-known Vitalait direct-by-mail service and not through the drug trade. Further information about either culture or service will be sent gladly on request.

Health Conference Successful—The annual meeting of the health officers' section of the League of California Municipalities was held at Stanford University September 21 to 23, with an attendance of about 150. An interesting program had been prepared and the attention of the health officers was held during each session. The entertainment features were enjoyed and at the final dinner, held in La Honda Canyon, William Simpson, health officer of Santa Clara County, and L. M. Powers, health commissioner of Los Angeles, were presented with appropriate gifts in recognition of their long service in the health officers' section as well as the thirty years and more of service that they have given in safeguarding the public health and their respective communities. Coronado was chosen as the meeting place for the 1923 conference of health officers.—State Board of Health Weekly Bulletin, September 23, 1922.

Kindly Mention This Journal When Applying

Dr. King's Sanatorium

(THE BANNING SANATORIUM)

Banning (Riverside County) California

This well known institution (for the treatment of tuberculosis of the throat and chest) has recently been rebuilt and enlarged. The City of Banning (suffering from phthisiophobia) passed a "zoning" ordinance that forced abandonment of the former site of this sanatorium. A new site was purchased. An injunction was sought to prevent the use of the new site for sanatorium purposes. A temporary injunction was granted but, at the final hearing, this injunction was dissolved and the right to build and maintain the sanatorium was established. Many of the most prominent physicians in the state contributed testimony that enabled us to win the suit. During the progress of these suits the institution found it difficult to provide for patients demanding admission. Now, however, in its new quarters, it is prepared to accept all who apply. To physicians who are unfamiliar with our work we will gladly furnish references to other physicians (in almost every town in California) who have had patients or relatives in this institution. A circular describing conditions and containing rates will be mailed upon request. Address

DRS. KING and BRAMKAMP. BANNING, CALIFORNIA.

DIRECTLY and INDIRECTLY

Liquid Peptonoids

IS AN IMPORTANT NUTRITIONAL AID IN THE SICK ROOM

DIRECTLY

BECAUSE it is acceptable when all other food is rejected *and* offers immediately available nitrogen *and* calories — in sufficient amounts to be *of* real importance in emergency feeding—THEREBY saving tissue waste *and* preventing collapse.

INDIRECTLY

BECAUSE it sets the digestive pendulum in motion, kindles the appetite *and* creates food tolerance — THUS speeding the moment when more substantial nourishment may be added to the dietary.

Also DRY PEPTONOIDS (Soluble). 40% Protein—51.5% Carbohydrate.

You do not speculate when you buy an investment bond

The interest rate on a bond is fixed and the ultimate payment of the principal is secured.

In the case of a Municipal bond, which is the obligation of a city, county or town in one of the States of the Union, the security behind the bond is the taxing power of the issuing municipality.

In the case of the Corporation bond, the security is a direct mortgage on actual property owned by the company. The corporation must pay interest on its bonds before declaring dividends on its stock issues.

Consequently a good sound bond is desirable as an investment for your savings because it means fundamental security and an assured, regular income of from approximately six to seven per cent.

Savings Banks, Life Insurance Companies, Trustees of estates and large investors, buy investment bonds because they combine high return with safety of principal. An increasing number of persons who heretofore have never purchased bonds are turning their attention to this method of investment.

Probably not again in this generation will good investment bonds offer such opportunities as at present. We will gladly mail you a list of sound investment bonds upon request.

The Romance of Radium

2. The First Production in America

IN 1911, Joseph M. Flannery of Pittsburgh, Pa., after much study and investigation, decided that the world needed more Radium and set about in his characteristically energetic way to produce it on a big scale in this country, and founded the Standard Chemical Company.

Deposits of Radium bearing ore (Carnotite) were discovered in southwestern Colorado and southeastern Utah, regions very wild and difficult of access. But Mr. Flannery found a way of getting out the ore and of refining it. And after two years of almost super-human effort, the first Radium to be produced on a commercial scale was refined in the Pittsburgh laboratory of Mr. Flannery's company, which has since produced about three-fourths of all the Radium now in use.

Our Service

An immediately available supply of standard radium tubes, needles and plaques, under seal of the United States Bureau of Standards; quality guaranteed by the Standard Chemical Company, the pioneer American and world's largest producer of radium.

Necessary instruments and screens for the safe handling and application of radium.

A comprehensive and scientific course of instruction in the physics and therapeutic use of radium.

A loose-leaf Compendium of Abstracts of professional papers, showing the technic and results of radium treatment, with supplements as issued.

"RADIUM"—a quarterly journal, the oldest publication devoted exclusively to the therapeutics of radium.

Complete installations of the latest apparatus for the collection, purification, tubing and measurement of radium emanation.

Medical and technical experts always available for conference or for advice by letter.

Skilled assistance in seeking lost radium.

Standardize with Castle

CASTLE

FROM roof to cellar, wherever sterilizing equipment was needed, the management of the Baptist Memorial Hospital at Memphis, Tenn., specified Castle Sterilizers as standard. In all, 16 units of Castle design and make were installed.

The hospital has been commended for its equipment. And rightly, because Castle once again proved its ability to interpret an institution's needs, and to build unusual sterilizing equipment to meet unusual needs.

Four pairs of Water Sterilizers were incorporated in large units. Their many refinements in construction and their famous ease of operation made them the proper basis for large and successful units.

It is never too late to standardize with Castle equipment.

What we have done for others we can do for you. Write us for free consultation.

STANDARDIZATION OF CLINICAL LABORATORIES

In order to have a definite plan to work on, Josiah J. Moore, Chicago (Journal A. M. A., September 9, 1922), says that a set of requirements for laboratories has been prepared and submitted to a large number of laboratory directors and pathologists, and from their comments and suggestions the following general standard requirements for clinical laboratories may be submitted: (1) The director of a clinical laboratory should be a medical graduate. (2) All interpretations of laboratory data should be made by doctors (of medicine, philosophy or public health) who are specialists in the branch of work to which the data pertain, i. e.: (a) Serologic, bacteriologic and chemical interpretations should be made by doctors who are trained serologists, bacteriologists and chemists. (b) Tissue diagnosis should be made by doctors of medicine who are experienced pathologists. (3) Technical procedures (methods) used in an acceptable laboratory should be the best available. (4) The equipment of an acceptable laboratory should be such that the proper technical procedures may be carried out. There should be ready access to current scientific books and journals. With reference to these suggested requirements, the following statement is made: (1) The director of a laboratory should be able to act as consultant in evaluating for his clients the various laboratory reports and in correlating them and other clinical data. (2) Many technical methods—most of them, perhaps—may be satisfactorily carried out by technicians. The data derived by such methods, however, should be interpreted by specialists. (3) If it is insisted that only the best modern methods be used in a laboratory, it follows that the technicians employed must be trained in these methods. (4) Clinical data and other pertinent information should accompany the submission of specimens or other material to the laboratory.

THE KROMAYER LAMP

Consider—

that the Kromayer lamp enjoys the distinction for highest intensity of Ultra-Violet radiation and the most practical means for administering treatment of many conditions.

The effective results obtained with its use over a period of ten years has been the stimulant for our scientific research work that has resulted in bringing the lamp to its present high state of efficiency.

It is chosen as the most desirable method of applying actinic rays to Lupus, Naevus, Acne, Psoriasis, Eczema, Ulcers and Wounds; to specific or non-specific orificial inflammatory conditions such as Tubercular Laryngitis, Rectal Fistulae, Otitis Media, Frontal Sinus Infections, Ozena and a number of gynecological conditions.

THE NEED FOR STRONGER STATE AND COUNTY SOCIETIES

"We need medical organization as never before, through which medical thought and medical leadership can be expressed. We need organization not to complain, object and resist, but to explain, direct and construct. We need it for mutual help and protection of the profession. We need it for the protection and welfare of the people. Always realizing that the State Medical Association depends on strong, active, loyal county societies and local academies of medicine, our efforts constantly should be exerted toward increasing the effectiveness of the central organization, which is the point of contact not only with governmental functions, but also with other state-wide and with national organizations and groups interested in allied issues. The mechanics of organization must be steadily added to and enlarged. Every eligible physician should be induced to become a member of his county and State association. I foresee in the not distant future a substantial increase in membership dues. Ten dollars a year per member for the State association should not be considered too large. It would be ridiculously small in comparison to membership dues in many other kinds of organizations."—Bulletin A. M. A., October 15, 1922.

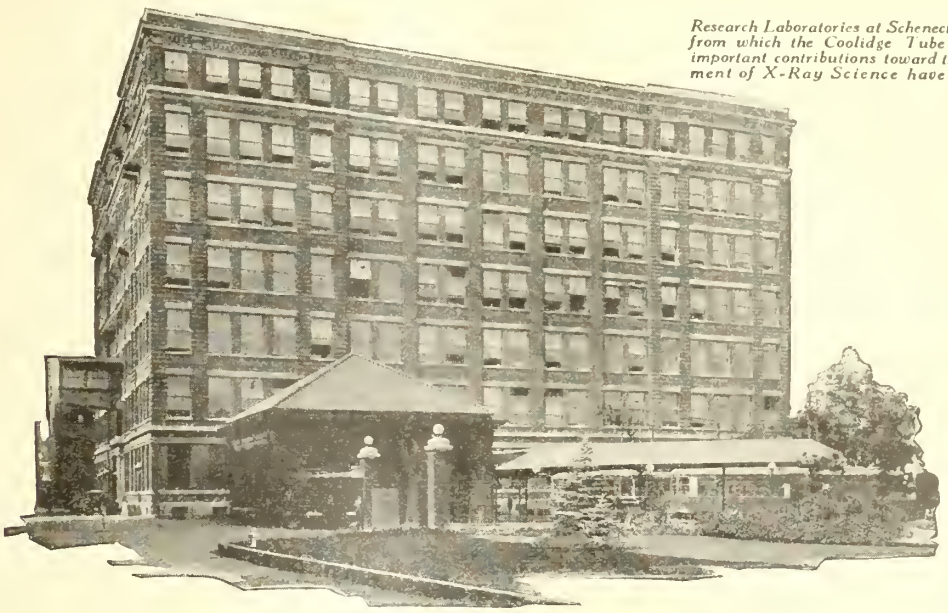
The MORTON HOSPITAL announces that they have purchased the former McNUTT or FAIRMONT HOSPITAL, 1055 Pine Street, San Francisco, and it is now open to the Medical Profession under the co-operative plan. The hospital has been thoroughly modernized and equipped with four Operating Rooms, Hydrotherapy, Electro-therapy, Thermopenetration, Helio-therapy, X-ray, Pathological and Clinical Laboratories.

Every physician will have equal privileges in the hospital.

MYRTLE BERESFORD
Secretary



Research Laboratories at Schenectady, N. Y., from which the Coolidge Tube and other important contributions toward the advancement of X-Ray Science have emanated

What Research Has Contributed to X-Ray Science

It is assumed by many general practitioners that X-Ray machines cannot be used in general practice because their maintenance and application require an engineering knowledge of electricity.

This was true once, but not now.

Improvements in Victor apparatus, the result of long-continued systematic research, have made it possible for the physician to use it in general practice, without imposing upon him the duty of becoming a physicist and engineer. X-Ray tubes are now standardized so that they need not be "nursed," as in the old days; dosages are now automatically controlled. The physician has simply to learn the manipulation of the apparatus, a comparatively simple task.

Through its Service Stations, located in the principal cities, the Victor X-Ray Corporation is prepared to instruct the physician in the proper method of operating Victor machines, to give him such guidance as he may require, and to maintain his machine in good condition.

In a word, Victor X-Ray machines can be installed and operated on a simpler basis than the more complicated electrical and mechanical apparatus to be found in the offices of many general practitioners.

The nearest Victor Service Station will gladly send a technically trained representative to any physician who may wish to investigate the suitability of Victor apparatus for his practice.

BARBITAL ABBOTT

For Refreshing sleep use this council-passed sedative.

For simple insomnia, for febrile cases, for nervous and hysteric patients, for the mentally disturbed, for surgical fright, for sea-sickness and for patients generally needing sleep or sedation—BARBITAL IS BEST.

BARBITAL, Abbott, is the same excellent hypnotic and sedative that formerly was introduced as veronal. The difference is one of name only. Use the ethical American name—BARBITAL—when prescribing. Specify the American made drug upon your blanks. See to it that your druggist has it in stock for your prescription needs.

BARBITAL, Abbott, is the equal of the best drug ever imported. There is none better.

Note These Reduced Prices

5-GRAIN TABLETS, 100: $1.65; POWDER, 1-OUNCE: $1.30

RED STAR BRAND NITROUS OXIDE AND MEDICAL OXYGEN

CARNEGIE INSTITUTE OF TECHNOLOGY

SCHENLEY PARK PITTSBURGH

Department of Chemistry,
26 August 1922.

REPORT ON THE ANALYSIS OF NITROUS OXIDE

Sample submitted by the Western Nitrous Oxide Company, San Francisco, California.

Carbon Dioxide	0.00 per cent
Oxygen	0.12 " "
Nitrous Oxide	98.89 " "
Moisture	0.67 " "
Nitrogen(by diff.)	0.32 " "
HCl	Nil
Chlorine	Nil
Oxides on Nitrogen NO and NO_2	Nil

L. H. Miller

L.H.Miller,
Instructor of Chemistry

NOTE—Analysis shows 98.89 per cent pure Nitrous Oxide, diluted 1.11 per cent, consisting of Oxygen, Moisture and Nitrogen, a dilution containing absolutely no harmful ingredient.

This sample was taken from a 420 gallon standard cylinder, which when empty holds at atmospheric pressure 1¼ gallons of atmospheric air, which is .31 per cent of the total 420 gallons in the sample submitted, making the manufacturing purity 99.20 per cent Nitrous Oxide.

CALIFORNIA STATE JOURNAL OF MEDICINE

Christmas Greetings

THIS number of the Journal concludes Volume XX of the California State Journal of Medicine and twenty years in the service of medical journalism. The files show a record of continuous improvement in the quality, size and usefulness of the Journal. Its various volumes and numbers indicate the progress in medical education, the practice of medicine, and public health in this state, and they chronicle the growth of membership of the State Medical Society.

The California State Medical Society was organized in 1856 with a few members, and has steadily increased until there are now 3605 members on the first day of December of this year. There are 6650 educated physicians practicing in California, and if the Journal is to meet its future obligations and if the State Society is to discharge its proper function adequately, both the membership of the State Society and the progress of the Journal must be stimulated.

The Journal wishes a **Happy Christmas** and a **Prosperous New Year** to all of its readers.

A DOCTOR'S STANDING IS MOST OFTEN MEASURED BY A FIRST IMPRESSION OF HIS OFFICE

Offices equipped with beautiful white aseptic steel furniture, particularly our "Porcello" ware, radiate sanitation and efficiency, thus producing a pleasing mental attitude in the minds of patients, especially the newcomers.

91-99 DRUMM ST. **Reid Bros** INCORPORATED SAN FRANCISCO

TOXIN-ANTITOXIN

New Formula

This product as originally used by Park of the Research Laboratories of the New York City Department of Health, and as heretofore prepared and marketed by us, has contained 3 L+ doses of diphtheria toxin in each dose, properly neutralized with antitoxin.

The directions given for its use provided that it be used on children from six months to six years of age. When used on older children and adults, it sometimes gave a reaction of undesirable severity.

In his more recent work, Park has been using in each dose a product containing 1/10 L+ dose of toxin, properly neutralized with antitoxin. The results of his preliminary studies show that an early immunity is produced equal to that established by the former product, and that no severe reactions occur even in older children and adults.

This work demonstrates a very marked improvement in diphtheria control that health officials will welcome, since it will permit the more universal use of Toxin-Antitoxin.

We are prepared to supply this newer product and to give full information upon request.

ANNOUNCING AN IMPROVED PRODUCT AT LOWER PRICES

Cilkloid

IMPERVIOUS SURGICAL DRESSING PERFORATED

The new process we have developed enables us to manufacture an improved form of tissue and at a cost that permits distribution at considerably lower prices than other materials now being used,

For SURGICAL—INDUSTRIAL—HOSPITAL Use

IMPERVIOUS CILKLOID excels for covering all wet packs and dressings, and for all purposes where rubber tissue, oiled silk and other impervious materials have been used in the past.

PERFORATED CILKLOID is perforated only from our double weight tissue to assure perfect safety for all direct dressings where a Non-Adherent Transparent Dressing is desired. Excels for Skin Grafts, Burns, Ulcers, Etc.

Place your order on this price list and mail to any Supply House or Dealer for immediate delivery.

The Management of an Infant's Diet

Mellin's Food contains 58.88 per cent of Maltose
Mellin's Food contains 20.69 per cent of Dextrins

a proportion of

Maltose and Dextrins

best suited to the carbohydrate needs of the average baby.

Mellin's Food contains 10.35 per cent of Cereal Protein.

Mellin's Food contains 4.30 per cent of Salts which consist mainly of Potassium Salts, Phosphatic Salts, and a small amount of Iron.

These facts should be considered in selecting a modifier of milk for infant feeding and these facts point out some of the reasons for the success of Mellin's Food which probably is unparalleled in any decade since the beginning of the study of scientific infant feeding.

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) $45.00 per week and upward.

ANNOUNCES

THAT ITS X-RAY DEPARTMENT IS NOW EQUIPPED

WITH A

MODERN DEEP THERAPY X-RAY APPARATUS

FOR THE

PRE- AND POST-OPERATIVE RADIATION OF DEEP MALIGNANCY

AND THE

TREATMENT OF INOPERABLE MALIGNANT CONDITIONS

This type of apparatus with its ability to produce a voltage of 280,000 volts (about twice the voltage capacity of X-ray machines hitherto available) gives an X-ray beam of enormously magnified penetrating power as compared to those previously in use.

Heavy filtration is used as an added factor in increasing the ratio of the depth to the skin dose, thus markedly decreasing the liability of injurious skin effects while as markedly increasing the effect on the deep tissues.

CORRESPONDENCE AND INSPECTION BY THE PROFESSION IS INVITED

Specialist in Women's Work — Three Competent Lady Assistants

FRANK F. WEDEKIND

2006 SUTTER STREET SAN FRANCISCO

Training in Sociology and Public Health an Essential in Medical Education—If we grant . . . that knowledge of remedial and preventive methods is of equal importance to the medical student, I am suggesting, for consideration, five essentials in the latter field which should be made a part of his medical education:

1. He needs to have a sympathetic understanding of the fundamental human problems in relation to the many complexities of modern life, and must become familiar with the trend of the best thinking along social lines.

2. He needs to know the place and function of sanitation in relation to the public welfare, the how and when and why of environmental influence on health. In other words, he needs to know when and how to make use of the knowledge of sanitary engineering, not necessarily himself to be a sanitary engineer.

3. He needs to be well grounded in the control of the communicable diseases and in bacteriology.

4. It is imperative that he should have a knowledge of hygiene, especially in its relation to the social and medical sciences which attempt to improve the race by approximating a solution of the basic problems of human existence; that is, the problems associated with the necessity for food, shelter, defense and propagation.

5. He needs to have a knowledge of psychology in its relation to conduct, with regard both to individuals and to groups, in order that he may truly educate both individuals and groups in right habits of action, by supplying motives which appeal to them.

The Council on Medical Education and Hospitals is recommending to the American Medical Association at this session that the last two years of undergraduate medical study be devoted to the four majors: practice of medicine, surgery, obstetrics and public health. The college will be asked to pay less attention to courses in special branches during the undergraduate term, and devote more time to the education of medical practitioners.

I believe that more attention to the subject outlined in the foregoing paragraphs will equip men to render a service to the individual and the community which will eventually bring the practice of medicine to a level of achievement undreamt of in the past. I believe that men who have received such preparation will be ready after their graduation to practice medicine in co-operation with the many and varied agencies for social betterment, with a greater degree of mutual understanding.—S. W. Welch, Jour. A. M. A.

FOR RENT

Physician wishes to share his offices—hours to be arranged; Schroth Building. Address Dr. B., care of State Journal, or Phone Sutter 5533.

Will board a normal, healthy child from infancy to ten years of age. A good home and mother's care. Best references given. Address Mrs. R. J. M., care of State Journal.

Belmont

Colfax Hospital for the Tuberculous

Convalescents with normal temperature taking the cure. A November Morning.

SITUATED in the foothills of the Sierra Nevada Mountains at Colfax, California, one hundred forty-four miles east of San Francisco on the Ogden route of the Southern Pacific Railway. Operated in conjunction with the Cottage Colony of the Colfax School for the Tuberculous and intended for the accommodation of those patients who are unable to bring attendants and live in the Colony. Patients are given daily medical supervision and enjoy the advantages of all approved modern methods of treatment. Terms reasonable. For further particulars apply to

ROBERT A. PEERS, Medical Director

Colfax, California

A HELPFUL FACTOR IN TUBERCULOSIS

"Cod-liver oil is valuable, because: Its large amount of unsaturated fatty acids permits it to be almost entirely absorbed, and thus furnishes a large amount of fat food. It promotes the absorption of other fats. It favors the deposit of calcium in the tissues."

—*Kirschner: American Review Tuberculosis, July, 1922.*

The "S. & B. Process"

Clear Norwegian (Lofoten) Cod-liver Oil

is guaranteed a one hundred per cent. product derived from the livers of fresh-caught, ***true Gadus Morrhuae,*** and affords the physician an admirable means of administering this nutrient, rich in fat-soluble vitamin, in a form exceptionally palatable.

Practice Limited to Ophthalmology

FOR SALE—Contract and private hospital in Northern California. Hospital building rather old, but adequate for work handled and includes good apartments for doctor. Contract work and industrial cases will support hospital, leaving private work entirely clear. No competition locally. Man should get on ground at once, so as to line up contracts for next summer. One and possibly two large new mills expect to run next summer. Have been sick part of time last two years and had to depend on assistants. Net receipts in 1919 were over $6000. Month of September, 1922, receipts over $1500. If man does own surgery can easily do 50 per cent better. Want $5000 for place. Will give terms. Live man should pay for place easily first year. Personal reasons for leaving. Can give possession in one month. Write for full details. Address Dr. A. A. Atkinson, Box 356, Motor Route "B," Sacramento, Calif. Special terms to anyone making deal before December 15, 1922.

"Female Weakness Cures"—The Propaganda Department of the American Medical Association has issued a new pamphlet under this title. The information ought to be given the widest possible publicity. Physicians may be able to do much good by reading the pamphlet and discussing with other physicians and friends the pernicious influence of these particular frauds. "Among the victims to quackery of every sort, women far outnumber men. They are always more trustful and, as a rule, find it more difficult, especially when suffering, to believe that any one can be base enough to abuse their confidence, much less to take advantage of their helplessness in order to plunder and injure them."

The list of alleged cures and treatments analyzed and exposed in this bulletin includes many "cures" extensively used in California and extensively advertised in certain quarters of this State. Some of them have headquarters in California. The following are some of the "cures" given in this pamphlet: "Acme Pennyroyal Pills," "Allan's Star Pills," "Alorine Antiseptic Suppository," "Alpen Seal," "Amenoretts," "Andrews' Wine of Life Root," "Annex Powders," "An-ti-seps," "Arthur's Emmenagogue Pills," "Astringent Herb Tablets," "Balm of Figs," "Wine of Cardui," "Cheeseman's Pills," "Chichester's Diamond Brand Pills," "J. Clarke's Female Pills," "Cotton Root Tablets," "Creole Female Tonic," "Dean Vaginal Suppositories," "Dean Female Pills," "Diamond Brand Pills," "J. H. Dye's," "Earl's Kidney and Bladder Pills," "Eastern Drug Co." "N. M. Ellis,' "Ergo-Kolo Female Compound, "G. E. Flood," "For-Me-Ka Oil Vitality," "Gerstle's Female Panacea," "Gold Medal Compound Pills," "Harmless Headache Powder," "Heart, Brain and Nerve Pills," " Hon's Healing Compound, Womb Relief, Womb Suppositories," "Hooper's Female Pills," "Hon's Invigorator Pills," "Moses Job," "King's Star Crown Pills," "Kremoids," "La Franco Combination Treatment and Vitalizer No. 209," "Leslie's Emmenagogue Pills," "Mammary Cell Food," "Martel's Female Pills, Special Female Pills," "Micajah's Wafers," "Mitchella Compound," "Mother's Friend," "Mott's Compound Female Pills," "Opaline Suppositories," "Orange Blossom Suppositories," "Pa-Nol," "Pehn-ix Nerve Vitalizers," "Pierce's Empress Tablets," "Pinkham's Vegetable Comp," "Piso's Tablets," "Porose Pills," "Red Cross Tansy Pills," "Royaline Oil," "Savatan," "Schade's Specific," "Snowdrop Tablets," "Stargrass Compound," "Stella-Vitae," "Strogal," "Thomas Emmenagogue Pills," "Viavi," "Vigor of Life," "Vigoroids," "Vimedia," "Vital Fire Remedy Co.," "Vitopian Home Treatment," "Watkins' Female Remedy," "Womb Tonic and Vitalizer Tablets," "Wrightsman's Sovereign Balm of Life," "Yale's Excelsior Fruiticura."

Statements That Merit Consideration

"At present, radium is undoubtedly the greatest single agent at our disposal in combating cancer." DOUGLAS QUICK, M. B., (Tor.), Attending Surgeon, Memorial Hospital, New York City.—*The American Journal of Roentgenology.*

"Radiotherapy of fibroid tumors is destined more and more to displace operation as patients learn to come early before contra-indications to its use have arisen." FRED. J. TAUSSIG, M. D., St. Louis, Mo.—*The Journal of the American Medical Association.*

IF YOU ARE INTERESTED IN THESE QUOTATIONS AND DESIRE FURTHER INFORMATION COMMUNICATE WITH OUR MEDICAL DEPARTMENT.

"The wave of opinion today among scientific research workers, is that toxic goiter is not a surgical disease.—After some years of experience and the assurance of my co-workers, I have arrived at the conclusion that radium is the treatment of choice." R. E. LOUCKS, M. D., F. T. M. C., Detroit, Mich.—*The American Journal of Roentgenology.*

Scientific and homelike sanitarium and hospital service. 55 minutes from San Francisco. Dairy products, poultry and vegetables fresh daily from Ross Sanitarium Farm.

Resident physician. X-Ray equipment. Complete laboratory and operating room service. Any member of A. M. A. can attend his own patients here if he wishes. Ideal for convalescent, chronic and rest-cure cases of all types. Competent staff and consultants available if desired.

THE SANITARIUM WITH A PERSONALITY

Address all communications to Medical Director, Ross Sanitarium, Ross, California

Diphtheria Antitoxin *and* Diphtheria Toxin-Antitoxin

PHYSICIANS have been specifying Parke-Davis Antitoxin for twenty-five years because it is dependable. In a disease in which life or death hinges on prompt and adequate immunization nothing must be left to chance. The patient has a right to every possibility of recovery; anything short of this would be false to the ideals of medical practice and subversive of the rights of humanity.

Medical men prefer Parke-Davis Antitoxin because it is pure, free from contamination, and certain of action. The potency and purity of the product are assured by every means known to biological science.

Toxin-Antitoxin, P. D. & Co., is rapidly winning similar recognition.

Active immunization is the end sought, and safety and efficiency of the product are predicated on proper mixing of the toxin and antitoxin. An improper mixture would result either in failure to protect, or in a dangerous reaction. Our Toxin-Antitoxin is so balanced as to insure the maximum immunizing effect consistent with safety.

"DIPHTHERIA IMMUNIZATION," a reprint, sent on request. Write nearest branch: Detroit, New York, Chicago, Kansas City, Baltimore, New Orleans, St. Louis, Minneapolis, or Seattle.

Parke, Davis & Company

Gastric Disorders

Gastric disorder is essentially a problem of nutrition. How and with what to feed become questions of vital importance.

That "Ovaltine" will nourish when other forms of nourishment are badly borne or rejected by the patient is the burden of numerous medical reports received from physicians in all parts of the world.

"Ovaltine" too, is well adapted to duodenal or rectal feeding. In the latter, reports show that it is well absorbed and effective in maintaining the general health of the patient until oral feeding can be resumed.

"Ovaltine" has been extensively used in such conditions as Gastric Ulcer, Gastritis, Gastric Carcinoma, Stomach Atony, the Dyspepsias or wherever there is Nausea, Anorexia or other obstacle to normal alimentation.

OVALTINE

Supplied by druggists at 50c, 80c, $1.50 and $5.00

Samples and literature mailed to physicians upon signed request.

The Wander Company, 37 South Wabash Avenue, Chicago

PITUITOL "WILSON"

An extract of the posterior lobe of the Pituitary Body, which the physician should specify, for the following reasons:

1. Cattle slaughtered in the abattoirs of Wilson & Co., under U. S. Inspection.
2. Glands removed under closely regulated conditions, by trained experts.
3. Glands chilled as fast as collected and delivered at once to the separate and modern plant of The Wilson Laboratories.
4. Posterior lobes carefully dissected by hand, by experienced workers, under ideal conditions of cleanliness and scientific supervision.
5. Extraction of the posterior lobe tissue carried out by chemists, with meticulous control over every step of the process.
6. Rigorous assay of the finished fluid, to assure proper strength, sterility and stability.
7. Liberal guarantee against deterioration. PITUITOL OBSTETRICAL is standardized at 3 times the strength required by the U. S. P. (Liquor Hypophysis).

ABDOMINAL SUPPORTS TRUSSES ELASTIC HOSIERY

Post-operative, maternity and hernia cases are especially well cared for in a unique and efficient manner. For twenty-one years we have made our business a study, and by confining ourselves to these specialties have developed methods that assure relief to the patient and satisfaction to the doctor.

Every physician should secure a copy of our catalogue, which explains our business in detail. We have the largest and best equipped plant on the Pacific Coast and are the exclusive agents for the famous Drs. Smith's "Honest John" Truss, the only practical device for holding at the internal ring.

ANNOUNCING

The Wappler Electric Company's latest model, "The Duplex X-Ray Machine." A double transformer machine for general radiographic and diagnostic work, and also designed to meet the demands of Deep Therapy up to a penetrative power of 200 K. V. at 6 M. A. Complete with Coolidge transformer control and meters at a price of $2200.

Write or call and discuss this outfit with us; it's real Wappler quality throughout, free from troublesome surges, gives long tube life, and has the kick.

Also ask for Bulletin No. 98 on the Wappler **Composite** X-Ray Unit—a universal table with tube stand attached, power plant and control in one assembly.

A Small Thing to Buy If You Never Need It.

"Gentlemen:
Just arrived home and hasten to enclose check for renewal. Would not be without such protection. Eternal vigilance against a suit affords a happy frame of mind that more than makes up for the cost.
Yours truly,"

"Gentlemen:
Enclosed find check; cannot afford to be without such contract, although I have practiced 25 years and never had a suit, yet the satisfaction of security is worth many times the amount asked.
Sincerely,"

"Dear Sirs:
I have carried a policy in your Company for many years without needing it but I am mighty glad to have it.
Very truly yours,"

"Gentlemen:
Enclosed find check. As yet we have never had a threat of law-suit but certainly feel the sense of security your policy affords us. The moral effect can be appreciated by anyone.
Respectfully,"

"Gentlemen:
Enclosed find check for current year's protection. I believe this is my 20th year. During these years, only once have I had a scare. I wouldn't live without your contract.
Yours truly,"

A Big Thing to Have By, if You Ever Need It.

"The Medical Protective Company
Fort Wayne, Indiana
Gentlemen:—I wanted to write to you the minute the foreman announced the verdict of the jury, 'Not Guilty.'

I have no words to express my appreciation of the way in which my case was handled from beginning to end. I am thoroughly pleased in every respect, and you can count on me to belong to your company as long as I practice.

The plaintiffs had an ex-judge for their attorney, and he certainly made a fight to win, but the ability of your attorneys certainly won the jury to our side.

Let me congratulate and thank you for the high-class, capable handling of our case.

If there is a Doctor who is doubtful about getting your insurance, refer him to me, and I will assure you that you will have another patron.

I thank you again for all the courtesies and kindnesses extended.
Very sincerely yours."

To the Medical Man or Woman Who Is Looking for an Ideal Country Home—For Personal Use or To Convert Into a Rest Home

I SUBMIT "OLIVECREST," Los Gatos. Situated in the foothills—above the frost line—between Saratoga and Los Gatos, where it commands a magnificent view of the valley, bay and mountains. The climate in this section is recognized as being one of the most even and healthful in the country. A soft water spring supplies plenty of water and I have city water as well.

In the property there are nearly three acres of sloping, fine soil, every bit being usable. At one side is a gully which could be cleared of underbrush and with its big oaks, easily made into a delightful trail with rustic nooks, etc.

Over 150 fruit trees furnish all sorts of tasty fruit, including prunes, oranges, lemons, figs, apples, peaches, olives, etc., as well as grapes, berries, etc. Several large oaks and a big cypress furnish ample shade in warm weather and with very little expense a swimming pool (for which there is ample water) and other recreational features, could be put in.

Improvements consist of an exceptionally well built 6-room house, a 3-room and bath cottage and large garage. The house is so made that a large annex could be put on one end at a moderate cost.

Photographs and any other data that might be desired will be sent on request.

Colfax School for the Tuberculous

Experience has shown that Sanatorium treatment is the most efficient and most approved method of treating the tuberculous. Those patients who are able to take advantage of the superior facilities offered by sanatorium treatment should not be denied the opportunity of receiving these benefits.

The cottage colony of the Colfax School for the Tuberculous provides accommodations for patients who have not only all the advantages of the sanatorium regime and supervision but at the same time have the benefit of home cooking and surroundings. While the patient improves the other members of the family daily receive instructions relative to those things everyone should know regarding tuberculosis.

Information regarding the methods of treatment and other details of interest to the physician and his patient are given in a booklet which will be sent on request.

WANTED—OFFICE SPACE. Physician who has recently come to San Francisco from the East desires to share office space and equipment adequate for the practice of internal medicine, with an established practitioner in medicine or any of the specialties. Afternoon hours only. Address Dr. R. F. R., care of State Journal.

PHYSICIAN, aged 30, married, Protestant, A. B. and M. D., Class A school, doing general practice in San Francisco, wishes to assist busy surgeon in this city (either general or special surgery). Am seeking good surgical training. Do not ask for remuneration. Address Dr. H. H., care of State Journal.

Health and Wealth—Health is conceded, theoretically, to be man's most valued possession, but when it comes to actually paying for it, a different attitude is assumed. Trained health officials (the only State or city officials, by the way, who are specially trained for their duties) are in this country, poorly paid. Not so in some other countries. The Medical Officer of Health of the city of Manchester, England, resigned a few months since. The City Fathers, in a fit of economy, put forth an advertisement for a new officer to be paid a salary of $7000. On the ground that this salary was not only inadequate for the responsibility attendant on the duties of the offices, but also insufficient when compared with the salaries of other city officials (the town clerk receiving $11,000), the British Medical Journal and Lancet refused to publish the advertisement. This was, of course, not only a protest of the journals but of the physicians whom they represent. As a result, the City Council took the hint and appointed a committee to confer in the matter with a committee representing the British Medical Association. The outcome of this conference was a compromise, the health officer to receive for the first two years $7500, for the succeeding two years $8750, and thereafter $10,000.—New York Medical Journal and Medical Record.

CONTRIBUTIONS

EXCLUSIVE PUBLICATION—Articles are accepted for publication on condition that they are contributed solely to this journal. Rules governing publication and method of preparing illustrations furnished on request.

POLICIES OF THE MAYO CLINIC

1. Every patient who comes to the Clinic receives the care and attention necessary without regard to financial status, social condition, race or creed. What he receives is measured by his necessities, not by his ability to pay. While the Clinic is ready and willing to give freely of its services to the worthy poor, each patient who is able to pay a fee is required to do so. The hospitals in Rochester are not owned by the Clinic, although under its medical and surgical direction. Every patient must be provided with money for his maintenance, hospital expenses, and transportation.

2. All the moneys that are received by the Mayo Clinic, beyond a reasonable and just return to its staff, are used to create endowments the income of which shall be devoted perpetually to the relief of human illness, to the advancement of research as to the cause and prevention of disease, and to medical education and such other welfare movements as are correlated with health problems.

3. The Mayo Clinic, its endowments, physical equipment, lands and other properties, are held by trustees in perpetuity for the sick of this and future generations.—Indiana Medical Journal.

These are worthy of imitation.

Co-operation—Of all the hard-worked words in our language, with the exception of poor, old, threadbare "efficiency," none is more abused than "co-operation." It is the shibboleth for every movement from birth control to Old Home Week. "Co-operation is promised." "Co-operation wins the day." "He will (won't, must) co-operate." Every change is rung on this once virile, useful word until it has almost been reduced to the level of the argot, a jargonesque shadow of its former self.—The Modern Hospital.

All approved forms of *Hydrotherapy,*—coupled where indicated with *Nauheim,* — *Hydro-Electric,* — *Radio Active Clay,* — *Calcic Carbonate,* — *Magnesia Carbonate* and *Sulphate Baths,* — *Radium Emanatorium.* Modern modifications of *Zander Apparatus, Massage* and *Manipulations. Electro-Therapy, Thermo-Penetration, Actino-Therapy, the Bergonie Treatment for Obesity, Proctoclysis, Corrective Gymnastics* and the application of tabulated *Physical Efficiency Tests.*

SERVICE RENDERED ONLY TO PATIENTS REFERRED TO US BY THE MEDICAL PROFESSION. NO OTHER CASES ACCEPTED

We are well equipped with modern mechanical devices of scientifically proven efficiency for the *Relief* of *Suffering.* We maintain a most comprehensive *Service Organization* of *Trained Attendants* rendering *Personalized Attention* to every patient.

The following chronic indications are most successfully treated at this Institute: *General Debility; Protracted Convalescence; Disorders of Nutrition* and the *Alimentary Tract; Cardio-Vascular* and *Renal Disorders; Functional Disturbances* of the *Nervous System; Ankylosed Joints; Muscle Atrophy; Defects* of *Physical Development.*

DOCTOR—Our Institute endeavors to meet a great and necessary co-operative role with the Physicians and Surgeons of San Francisco and Bay Cities, in their fight with intractable morbid conditions. Our Institute is simply a unique and efficient therapeutic agent, available to all reputable physicians who want to retain their patients, but desire to place them in the hands of specially trained technicians who are equipped with the required modern therapeutic appliances and experience, and who make a specialty of coping with conditions described.

Improvements are constantly being made in all departments, both in equipment and methods, in an earnest effort to keep pace with the foremost rank of progressive scientific medicine.

WHY NOT INVESTIGATE THOROUGHLY ABOUT US TODAY?

INSPECTION INVITED

THOSE physicians who have been called in the night to administer diphtheria antitoxin to a child appreciate the importance of a simple, workable syringe package.

The Lilly Syringe is an index to the merit of its contents. Its preparation for injection involves no loss of time or unnecessary effort. With it you can meet emergencies with confidence and assurance.

The only satisfactory way to become acquainted with this superior syringe is to use it. Ask your druggist to supply Lilly's Diphtheria Antitoxin. Write us for further information.

MEAD'S

Infant Diet Materials

Like many good things there is no mystery about Mead's Ethical Policy—but there is MUCH OF GOOD SENSE

Mead's Slogan—"Consult the Doctor First"

"MEAD'S DEXTRI-MALTOSE is an ethical infant diet material offered to physicians who wish to modify cow's milk for the individual requirements of babies."

MEAD'S "D-M" is not advertised in women's magazines, newspapers or any lay publications.

MEAD does not print feeding directions on the "D-M" package.

Satisfactory results—because the doctor's creative talent has full scope and he is not hindered by "outside interference."

A quality product marketed in this ethical manner must necessarily give results in most cases, since it is offered only for the consideration and approval of physicians.

THE DOCTOR'S CONFIDENCE IS NOT MISPLACED

THE MEAD JOHNSON POLICY

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant. Literature furnished only to physicians.

28,000 doctors asked us for literature this year
Will you please write for some, too?

BACILLUS

ACIDOPHILUS

Remarkable results are reported in the journals from the use of this bacillus in cases of intestinal disorder. Practically all of the investigators agree that this organism should be taken in milk.

We offer a bacillus acidophilus of unusual vigor, grown in milk. Many physicians are attaining success in the treatment of intestinal toxemias by the use of our strains of this bacillus, either in a pure culture or in symbiosis with the bacillus Bulgaricus.

Our cultures are distributed by the well-known Vitalait direct-by-mail service and not through the drug trade. Further information about either culture or service will be sent gladly on request.

HEART STATION

A Laboratory
for the Investigation of Cardiac Conditions Only

Inviting your co-operation, we offer the following diagnostic aids, any of which may be ordered separately. We particularly recommend the X-Ray examination.

X-RAY EXAMINATION:

We devote our entire time to the Heart; have specially constructed apparatus and are in a position to give the heart an intensive X-Ray study.

Radiograms, Fluoroscopic Examination, Ortho-cardiograms and Patterns.

ELECTROCARDIOGRAMS:

As a diagnostic aid in many Cardiac conditions, Electrocardiograms are almost indispensable. They frequently aid in prognosis and in judging the effect of Therapy.

METABOLISM:

We are equipped with a portable apparatus, so Tests may be made at your patient's home, your office, or at my office, as you wish.

Vital Capacity, Function Tests, etc.

Suggestions as to therapy, etc., given any time on request.

A separate department is maintained for the physical training of Cardiac cases only.

Dr. King's Sanatorium

(THE BANNING SANATORIUM)

Banning (Riverside County) California

This well known institution (for the treatment of tuberculosis of the throat and chest) has recently been rebuilt and enlarged. The City of Banning (suffering from phthisiophobia) passed a "zoning" ordinance that forced abandonment of the former site of this sanatorium. A new site was purchased. An injunction was sought to prevent the use of the new site for sanatorium purposes. A temporary injunction was granted but, at the final hearing, this injunction was dissolved and the right to build and maintain the sanatorium was established. Many of the most prominent physicians in the state contributed testimony that enabled us to win the suit. During the progress of these suits the institution found it difficult to provide for patients demanding admission. Now, however, in its new quarters, it is prepared to accept all who apply. To physicians who are unfamiliar with our work we will gladly furnish references to other physicians (in almost every town in California) who have had patients or relatives in this institution. A circular describing conditions and containing rates will be mailed upon request. Address

DRS. KING and BRAMKAMP. BANNING, CALIFORNIA.

Bonds of Hydro-Electric Power Companies

With Public Utilities furnishing electric power for lighting, commercial and other purposes, there are two methods used in generating the power, one being a manufactured force, usually steam, the other a natural force, water.

The advantages of using water instead of steam may readily be seen.

With the steam plant, coal and other material must be used, and the prices of these commodities fluctuate; with increased prices naturally the cost of production is increased.

By the use of water, the force is supplied and replenished by Nature with but the slightest dependence upon material and its cost. Furthermore, to operate a hydro-electric property but few men are required, and this to a large degree eliminates the labor factor, which under existing economic circumstances is a very important item to be considered.

The hydro-electric power company furnishes a service essential to the progressive community. Low overhead expense, low capital requirements, minimum dependence upon human labor and unbroken records of growth in earnings over long periods of time are some of the factors which insure the stability of its bonds.

Should you care to consider such issues for investment of your surplus funds, we shall be glad to make specific offerings upon request.

The Romance of Radium

3. Comparison of Ores

THE European pitchblende ores with which Madame Curie worked yielded about one gram of Radium to every five or six tons. In the case of our Colorado-Utah ore, (Carnotite) 400 to 500 tons are required to produce a gram of Radium, and to secure this amount of milling ore, it is necessary to hand sort it from several thousand tons of worthless material.

In spite of this apparent handicap the Standard Chemical Company has led the world in the production of Radium, being the pioneer American and world's largest producer.

Our Service

An immediately available supply of standard radium tubes, needles and plaques, under seal of the United States Bureau of Standards; quality guaranteed by the Standard Chemical Company, the pioneer American and world's largest producer of radium.

Necessary instruments and screens for the safe handling and application of radium.

A comprehensive and scientific course of instruction in the physics and therapeutic use of radium.

A loose-leaf Compendium of Abstracts of professional papers showing the technic and results of radium treatment, with supplements as issued.

"RADIUM"—a quarterly journal, the oldest publication devoted exclusively to the therapeutics of radium.

Complete installations of the latest apparatus for the collection, purification, tuhing and measurement of radium emanation.

Medical and technical experts always available for conference or for advice by letter.

Skilled assistance in seeking lost radium.

Labels Under the Prohibition Law—According to D. R. Enness (Medical Review of Reviews): "The term 'alcohol' does not designate a specific chemical compound, but is the designation of a group and, at that, a very large one of chemical compounds differing chemically and, . . . physiologically, when taken internally, from each other. The individuals belonging to this group all contain an atom of hydrogen combined with an atom of oxygen, which characterizes them chemically and which combination of oxygen and hydrogen is called the hydroxyl radical. The rest of the molecules of these bodies may contain almost any other element and combination of elements; if and as long as they only contain the hydroxyl radical they are alcohols. When more than one of these radicals are present in the molecules, the alcohol is termed a di-alcohol, tri-alcohol, etc. Thus, compounds like glycerin are alcohols. When, therefore, our Government requires our labels on alcoholic beverages to give the amount of alcohol they contain, it supplies the public only with very incomplete and ineffectual information. For it is of equal, if not even of greater importance, to know what is the nature of the alcohol (alcohols) present, and not only the percentage amount of the total alcohol. Thus, a beverage may contain a larger percentage of alcohol and still be less harmful than one containing very much less alcohol. If the prohibition law would, as I believe has been suggested, prohibit all drinks containing more than one-half of one per cent of alcohol, chemists would still be able and allowed to produce beverages which would be intoxicating and even dangerous to life, providing only they select stronger alcohols from the enormous group of alcohols from which they can draw. For, as stated above, these alcohols differ very materially in their physiological effect and action. Thus, it is stated, that ethyl-alcohol, the commonest one of the whole group and the main product of the general fermentation process, will produce intoxication in a rabbit in a dose of 7 grams, while of butyl-alcohol, also a product of the ordinary fermentation process, only 3 grams, and of iso-amyl-alcohol even less is necessary. Two grams alone of the latter will produce a semi-sleepishness. Of butyl-alcohol 7 grams will produce death in a rabbit, while 7 grams of ethyl-alcohol only produce intoxication, as stated above. Therefore, even if the law would limit the term 'alcohol' to alcohols of the fermentation process, still there would be a lack of definiteness, as is already seen from the above referred to alcohols. For this designation would include alcohols of widely different physiological action. Besides, the process of fermentation produces compounds not belonging to the alcoholic group of equally and even, at times, more deleterious character. These may in whole or in part be responsible for the intoxicating effect of fermented beverages. Of these non-alcoholic compounds no mention is made in the law. It is, therefore, clear that a label stating only the percentage amount of alcohol without giving the nature of the alcohol is very incomplete and unsatisfactory information by means of which to safeguard the public."

A Physician's Function—My function as a physician is not discharged when I say to a solicitous client, "There is nothing the matter with you," unless that opinion is fully accepted. And if my patient continues to believe there is something the matter with him, there is something the matter with him, and my function has not been fulfilled until I have made him see, as I see, that he is not in jeopardy.—Henry B. Faville, Pennsylvania Medical Journal.

THE SHEPPARD-TOWNER ACT IN RELATION TO PUBLIC HEALTH

On the basis of figures presented by Anna E. Rude, Washington, D. C. (Journal A. M. A., September 16, 1922), it is estimated that approximately 13.6 per cent of the total births during the year 1920 occurred in hospitals. This percentage varied from 1.7 in Arkansas and Mississippi, to 40.1 in Illinois. Though these figures are only approximate, because of the admitted limitation of the questionnaire method, they at least point significantly to several phases of the hospital problem in relation to obstetrics. They show that there is hospital provision for approximately 40 per cent of the births in the United States, but that only 14 per cent of the births during 1920 occurred in hospitals. In this lack of utilization of available hospital facilities for confinement care are involved three important problems: (1) cost of hospital care; (2) inaccessibility of hospitals, and (3) lack of knowledge concerning the advisability of hospital care. Many other equally important problems await solution in connection with the hygiene of maternity and infancy. The Sheppard-Towner Act is limited to a five-year period. Its fundamental purpose is to enable States to demonstrate for themselves the value of such work in terms of life saving and improved health, and to stimulate them to develop more complete programs for making such work effective. The protection of maternity and infancy is not the function of one isolated group, but is dependent on the obstetrician, the pediatrician, and general practitioner, the public health nurse and the social worker in co-operation with the public health authorities. In addition, it is dependent on the co-operation of an enlightened public.

YOUR DUTY, DOCTOR, HAVE YOU DONE IT?

1. Are you more concerned in your own personal privileges than you are in your brother practitioners?

2. How often do you attend the meetings of your Medical Society? What for?

3. Do you assume that the Medical Society will extend to you the benefits of the Association without any effort on your part?

4. Do you realize how much you can do to assist your brother practitioners in fighting the menaces confronting the profession?

5. If you do realize it, have you done your part in helping to combat the evils?

Every physician has an inalienable partnership in his medical association; the prosperity of the organization rests with each individual.

It is essential to alert membership that every individual has an understanding of the needs of the association and a loyalty to carry out its policy, and that you give the keenest co-operation to your fellow members and the officers of the organization.

When you grasp this spirit then you will be a worthy member of the medical profession and will become a contributor to the force that is necessary to make the organization serve the end for which it was intended. (Editorial, Illinois Medical Journal, October, 1922.)

Directory of Hospitals of California

ALEXANDER SANATORIUM
Nervous and Mild Mental Diseases
Belmont, Calif.

ANDERSON SANATORIUM
Mental and Nervous Diseases
2535 Twenty-fourth Avenue
Oakland, Calif.

BANKSIA PLACE SANITARIUM
Nervous and Mental Diseases
5227 Santa Monica Boulevard
Los Angeles

BURNETT SANITARIUM
Limited General Hospital
Fresno, Calif.

BYRON HOT SPRINGS
Mineral Springs and Baths
Byron Hot Springs, Calif.

CALIFORNIA SANITARIUM
For the Treatment of Tuberculosis
Belmont, San Mateo County, Calif.

CANYON SANITARIUM
For the Treatment of Tuberculosis
Redwood City, Calif.

HELIOS SUN SANITARIUM
Sun and Outdoor Treatment of Tuberculosis and Other Chronic Diseases
San Rafael, Marin Co., Calif.

HOSPITAL FOR CHILDREN AND TRAINING SCHOOL FOR NURSES
General Hospital for Women and Children
3700 California Street, San Francisco

COLFAX HOSPITAL FOR THE TUBERCULOUS
For the Treatment of Tuberculosis
Colfax, Calif.

COLFAX SCHOOL FOR THE TUBERCULOUS
A Cottage Colony for the Tuberculous
Colfax, Calif.

ANNOUNCEMENT

Members of the Medical Society of California, Advertisers in the State Journal, or any individual or firm authorized by the Medical Society may now have access to the only

Official Mailing List

of the

MEDICAL SOCIETY OF THE STATE OF CALIFORNIA

This list comprises *all* the members of the Medical Society, arranged by counties, and is carefully kept up to date, being revised every thirty days.

By authority of the State Council, we are permitted to offer you the use of this list for any legitimate addressing purpose. APPROVAL OF THE SECRETARY OF THE STATE SOCIETY IS ESSENTIAL IN ALL CASES.

The rates are reasonable and you are assured of having your addressed matter *reach* the parties addressed.

WRITE OR PHONE

THE JAMES H. BARRY COMPANY

1122-1124 Mission Street, San Francisco

Phone Park 6380

Note:—All addressing is handled under the personal supervision of Mr. Wm. H. Barry, Superintendent of Publications, Medical Society of the State of California.

HOSPITAL FOR CHILDREN AND TRAINING SCHOOL FOR NURSES

A general hospital of 275 beds for women and children.
Thirty beds for maternity patients in a separate building, newly equipped.

Complete services of all kinds for women and children.
Infant feeding a specialty.

House staff consists of three resident physicians and eight internes.

Accredited by the Council on Medical Education and Hospitals of the American Medical Association.

Institutional member of League for the Conservation of Public Health.

The oldest school of nursing in the West.

Director of Hospital
Dr. J. B. Cutter

Assistant Superintendent
Mrs. Hulda N. Fleming

Superintendent of Nurses
Miss Ada Boye, R.N.

What This Simplified X-Ray Apparatus Means

A Good Diagnostic Radiograph for Every Exposure

This is now possible to the user of the Victor Stabilized Mobile X-Ray Unit—no longer need he await years of experience to arrive at this point of efficiency.

Guesswork Practically Eliminated

The "hit and miss" method of taking radiographs must now give way to this improved apparatus which enables the operator to duplicate his best results, from day to day and month to month, simply because the machine will deliver repeatedly the exact current desired for a given technique, regardless of voltage fluctuations occurring on the supply line from which the machine is energized.

Tube Current Is Stabilized

When the voltage of the line supply current fluctuates (this condition prevails on practically every line), the Victor-Kearsley Stabilizer, incorporated in this unit, acts automatically to hold constant the exact milliamperage desired for the radiograph. 100% radiographic results are therefore insured—no "retakes" necessary because of the fluctuating line supply.

Circuit Breaker Safety Device

In case of "overload" beyond the capacity of the tube (30 Ma. at 5" back-up spark), a circuit breaker *automatically* shuts off the current supply, preventing damage to tube and apparatus. Consider also the importance of this from the standpoint of protection to both operator and patient, in case of accidental contact with the high tension system.

The Victor-Kearsley Stabilizer is one of the most important X-Ray developments since the advent of the Coolidge Tube itself. It should not be confused with other devices which tend to stabilize only the current to the filament of the tube. The important advantages of this unit are fully explained in a special bulletin, which we will gladly send you on request.

Important Announcement to the Medical Profession

THE ABBOTT LABORATORIES takes pleasure in announcing the purchase of the property, good-will and equipment of the DERMATOLOGICAL RESEARCH LABORATORIES of Philadelphia, where it will continue the manufacture of the well-known "D. R. I." brands of ARSPHENAMINE and NEOARSPHENAMINE.

Dr. Geo. W. Raiziss, head of the Department of Chemistry, will continue to direct the production of these products, assisted by his entire corps of trained chemists in the Dermatological Research Laboratories.

THE ABBOTT LABORATORIES has acquired the right to use the designation "DERMATOLOGICAL RESEARCH LABORATORIES PRODUCTS." This notable addition to the ABBOTT service became effective November 1. The same high standards of purity and the same sales policies will be continued. Orders will be filled promptly from the DERMATOLOGICAL RESEARCH LABORATORIES, Philadelphia, or from local distributors in all large cities.

RED STAR BRAND NITROUS OXIDE AND MEDICAL OXYGEN

CARNEGIE INSTITUTE OF TECHNOLOGY

SCHENLEY PARK PITTSBURGH

Department of Chemistry,
26 August 1922.

REPORT ON THE ANALYSIS OF NITROUS OXIDE

Sample submitted by the Western Nitrous Oxide Company, San Francisco, California.

Carbon Dioxide	0.00 per cent
Oxygen	0.12 " "
Nitrous Oxide	98.89 " "
Moisture	0.67 " "
Nitrogen(by diff.)	0.32 " "
HCl	Nil
Chlorine	Nil
Oxides on Nitrogen NO and NO_2	Nil

L.H. Miller

L.H.Miller,
Instructor of Chemistry

NOTE—Analysis shows 98.89 per cent pure Nitrous Oxide, diluted 1.11 per cent, consisting of Oxygen, Moisture and Nitrogen, a dilution containing absolutely no harmful ingredient.

This sample was taken from a 420 gallon standard cylinder, which when empty holds at atmospheric pressure 1¼ gallons of atmospheric air, which is .31 per cent of the total 420 gallons in the sample submitted, making the manufacturing purity 99.20 per cent Nitrous Oxide.

WESTERN NITROUS OXIDE COMPANY

LABORATORY: TENTH & FOLSOM STS.

FEE SCHEDULE
(Revised May 1, 1922)

BLOOD—	
Leucocyte Counts $3.00 } Differential Leucocyte counts 3.00 } $5.00	$ 8.00
Red blood counts 3.00 } Hemoglobin determinations 3.00 } $5.00	
Blood cultures	15.00
Blood smears for blood parasites, as malarial plasmodia	3.00
Blood group tests	5.00
Blood Chemistry (sugar, urea nitrogen, non-protein nitrogen, creatinin, uric acid, CO_2 combining power), single item	5.00
Each additional item	3.00
Wassermann tests—blood	5.00
Widal (agglutination) test	3.00
Coagulation and bleeding times	5.00
URINE—	
Urinalysis, routine	3.00
Phenolsulphonephthalein excretion	5.00
Microscopic examination for tubercle bacilli	3.00
Bacteriologic examination	5.00
STOOLS—	
Microscopic examination of stools	5.00
Examination of stools for invisible blood	3.00
Bacteriologic examination for typhoid and dysentery group	15.00
STOMACH CONTENTS—	
Chemic and microscopic examination of stomach contents	5.00
Test meal and obtaining contents for examination	5.00
SPUTUM—	
Microscopic examinations for tubercle bacilli	3.00
Pneumococcus typing with mouse method	15.00
Cultural examination	10.00
EXUDATES—	
Bacteriologic and microscopic examination of exudates	5.00
Diphtheria	5.00
Cerebro-spinal fluid examinations for syphilis (Wassermann test, cell count, globulin test)	8.00
Colloidal Gold test	5.00
Microscopic examination of smears, as for gonococci and Vincent's angina, sent to the laboratory	3.00
LUMBAR PUNCTURES (without examination of fluids)	10.00
VON PIRQUET TUBERCULIN TEST	5.00
DARK FIELD EXAMINATION for spirochaetes	10.00
TISSUES—	
Tissue examination	10.00
Pathologic consultation at operation (frozen sections when necessary)	25.00
VACCINES—BACTERIAL	10.00
WATER—	
Bacteriologic examination	15.00
MILK—	
Chemic examination	5.00
Bacterial count	5.00
ANIMAL INOCULATION for tubercle bacilli	15.00
BASAL METABOLISM DETERMINATION	15.00
BLOOD TRANSFUSION (not including cost of donors)	$100.00 to 150.00
EXAMINATION OF ANIMAL BRAINS FOR RABIES	15.00
ANTI-RABIC TREATMENT, 21 injections, including vaccine material	150.00

POST-MORTEM examinations by special arrangement.

OTHER LABORATORY EXAMINATIONS — FEES ON REQUEST

INTRAVENOUS and Intraspinal therapy (Intravenous serum, glucose, salt solution and Intraspinal serum) — Fees on request
